HowTo BGX

Ernest Turro Imperial College London

April 25, 2007

1 Introduction

This vignette describes how to use bgx, a C++ implementation of a Bayesian hierarchical integrated approach to the modelling and analysis of Affymetrix GeneChip arrays. The model and methodology is described in Hein et al, 2005.

There are two ways to run bgx: (1) through R and (2) as a standalone binary. Both ways make use of probe level GeneChip data, which you must obtain as GeneChip CEL files.

2 Reading in the CEL files

When you load bgx, several required packages from the Bioconductor¹ project are automatically loaded.

> library(bgx)

The affy package allows you to read CEL files into an AffyBatch object. This can be achieved by changing your working directory to wherever the CEL files are stored and executing:

> aData <- ReadAffy()</pre>

This will read in the CEL files in alphabetical order and save the data in the aData object. Alternatively, you can specify the specific files you would like to read in by adding their paths to the argument list, for example:

> aData <- ReadAffy("CEL/choe/chipC-rep1.CEL", "CEL/choe/chipS-rep2.CEL")

¹http://bioconductor.org

3 Running BGX through R

A basic execution of the program can be performed by simply passing an AffyBatch object as a single parameter to the bgx function and saving the result in an ExpressionSet object. The result will hold array-specific gene expression values and their corresponding standard errors in assayData(eset)\$exprs and assayData(eset)\$se.exprs respectively.

> eset <- bgx(aData)</pre>

A more elaborate scenario would involve splitting the arrays into a number of conditions using the *samplesets* argument²; specifying which genes to analyse with the *genes* argument; specifying whether to take into account probe affinity with *probeAff*; setting the number of burn-in and post burn-in runs with the *burnin* and *iter* arguments respectively; setting the set of parameters to save with the *output* argument³; and specifying where to save the runs with *rundir*. Execute help(bgx) in R for a full explanation of all the parameters.

As an example, let us analyse the Dilution data set and save the results in the current working directory ("."):

- > library(affydata)
- > library(hgu95av2cdf)
- > data(Dilution)

> eset <- bgx(Dilution, samplesets=c(2,2), probeAff=FALSE, burnin=2048, iter=8192,ge

The eset object will contain gene expression information for each gene under each condition (not necessarily each array). You may obtain the gene expression measure using the exprs function. For instance:

> exprs(eset)[10:40,] # Shorthand for assayData(eset)\\$exprs[10:40,]

	condition 1	condition 2
947_at	6.54444	6.25029
948_s_at	4.84583	4.45123
949_s_at	4.84665	4.55750
950_at	4.48827	4.27474
951_at	2.70152	2.49357
952_at	1.58622	1.94747
953_g_at	5.28392	4.89309

 $^{^2}$ Note that if your AffyBatch object contains information on the experimental design in the phenoData slot, you do not need to use the samplesets argument.

³ output can be set to either "minimal", "trace" or "all". See the documentation for an explanation of what these levels mean

```

Run help(ExpressionSet) in R for more information.

Note that samplesets should be set to an array specifying the number of replicates in each condition. If set to (3,2), bgx will treat the first three arrays read into R as replicates under condition 1 and the next two as replicates under condition 2. You should make sure that all condition 1 files are read in first and all condition 2 files are read in second by ReadAffy(). You may check the order of the samples in your AffyBatch object by using the sampleNames function:

```
> sampleNames(Dilution)
```

```
[1] "20A" "20B" "10A" "10B"
```

4 Running BGX as a standalone binary

Occasionally it may be useful to run bgx as a standalone binary from the command line⁴. In this case, you should use the standalone.bgx function instead of the bgx function.

⁴You can compile it by tweaking 'src/Makefile.standalone' to your specifications and running 'make -f Makefile.standalone' from the 'src' directory.

It takes the same arguments as bgx, with the addition of *dirname*, which should specify where you would like to save the input files required by the standalone binary.

```
aData <- ReadAffy() # Read in 6 arrays across two conditions

# in alphabetical order

standalone.bgx(aData, samplesets=c(3,3), genes=c(1:650,1000:1200),

burnin=16384, iter=65536, output="minimal",

dirname="input-choe3replicates")
```

Once you have saved the input files, you should locate the binary, make sure it is executable⁵, and pass the path to the newly created infile.txt file as a single argument. For example:

```
./bgx ../input-choe3replicates/infile.txt
```

5 Detailed analysis of the output

If you wish to analyse the output in detail, you should first read the output into a list as follows:

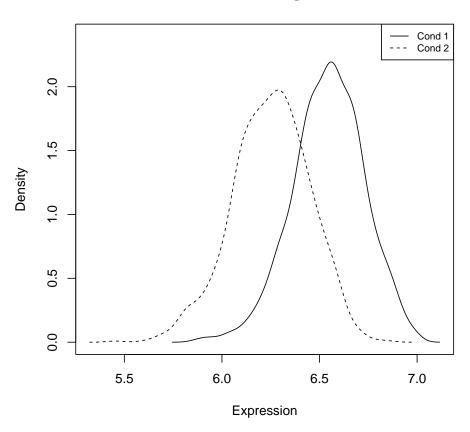

```
> bgxOutput <- readOutput.bgx("run.1")</pre>
```

You may then pass the bgxOutput object to any of several analysis functions. For instance, to view the gene expression distributions under the various conditions for gene 10, you could do:

> plotExpressionDensity(bgxOutput, gene=10)

⁵Under Unix-like environments, you can type chmod +x bgx at the command prompt to do this.

Densities of mu for gene 947_at

In order to get a list of ranked differential expression values, you could do:

- > rankedGeneList <- rankByDE(bgxOutput)</pre>
- > print(rankedGeneList[1:25,]) # print top 25 DEG
