Package ‘CFAssay’

April 25, 2017

Type Package

Title Statistical analysis for the Colony Formation Assay

Version 1.10.0

Date 2017-02-10

Author Herbert Braselmann

Maintainer Herbert Braselmann <braselm@helmholtz-muenchen.de>

Depends R (>= 2.10.0)

Description The package provides functions for calculation of linear-quadratic cell survival curves and for ANOVA of experimental 2-way designs along with the colony formation assay.

**cellsurvLQdiff**

Comparison of two linear-quadratic cell survival curves

**Description**

The function does an ANOVA test for overall comparison of the parameters \textit{alpha} and \textit{beta} of two linear-quadratic cell survival curves. The parameters are fitted simultaneously to the data with this function, i.e. no other function is necessary to derive the fits.

**Usage**

```r
 cellsurvLQdiff(X, curvevar, method="ml", PEmethod="fit")
```

**Arguments**

- \texttt{X}: A data frame which contains columns \textit{Exp}, \textit{dose}, \textit{ncells}, \textit{ncolonies} and a further column containing two different values (character strings), which identify the two curves. Moreover, if there is no 0-value in the \textit{dose} column, \texttt{X} has to contain a column \textit{pe} for plating efficiencies.

- \texttt{curvevar}: Character string, which has to be one of the column names of the data frame \texttt{X}, that contains the two different values (character strings that distinguishes between the two curves).

- \texttt{method}: Determines the method used for the fit. "ml" is for maximum-likelihood, "ls" for least-squares. "franken" performs weighted least-squares with weights as described in Franken et al. (2006).

- \texttt{PEmethod}: Controls the value of the plating efficiencies, i.e. the colony counts for untreated cells. "fit" calculates fitted plating efficiencies as model parameters, "fix" uses fixed ones calculated from the observed zero dose data or from a column named \textit{pe} in \texttt{X}.

**Details**

In the data frame \texttt{X}, \textit{Exp} identifies the experimental replicates and may be numeric or non-numeric. \texttt{method="ml"} for maximum-likelihood uses R function \texttt{glm} with family "quasipoisson" and link function "log". \texttt{method="ls"} uses R function \texttt{lm}.

**Value**

The function returns an object of class \texttt{cellsurvLQdiff} containing three elements, \texttt{fit1}, \texttt{fit2} and \texttt{anv}. \texttt{fit1} and \texttt{fit2} are objects of class \texttt{glm} when \texttt{method="ml"} or of class \texttt{lm} when \texttt{method="ls"}. \texttt{fit1} has parameters \textit{alpha} and \textit{beta} fitted in common for both cell survival curves. \texttt{fit2} has parameters \textit{alpha} and \textit{beta} fitted differently for both curves. \texttt{anv} is of class \texttt{anova} and contains the F-test. Test results are printed, however, the full result including curve parameters is returned invisibly, i.e. the function has to be used with \texttt{print} or assigned to a variable, say for e.g. \texttt{fitcomp} as in the example below.

**Author(s)**

Herbert Braselmann
**cellsurvLQfit**

**Fit the linear-quadratic (LQ) model to cell survival data**

**Description**

This function calculates the linear coefficient \( \alpha \) and the coefficient \( \beta \) of the dose-squared term (see manual for this R-package) for colony counts measured for a set of irradiation doses and repeated experiments. The function is a wrapper for the R-functions `glm` or `lm`, which simplifies use of these functions for cell survival data.

**Usage**

```r
 cellsurvLQfit(X, method="ml", PEmethod="fit")
```

**Arguments**

- `X` A data frame which contains at least columns `Exp`, `dose`, `ncells`, `ncolonies` and if there is no 0-value in the dose-column, `X` has to contain a further column `pe` for plating efficiencies.

- `method` Determines the method used for the fit. "ml" is for maximum-likelihood, "ls" for least-squares. "franken" performs weighted least-squares with weights as described in Franken et al. (2006).

- `PEmethod` Controls the value of the plating efficiencies, i.e. the colony counts for untreated cells. "fit" calculates fitted plating efficiencies as model parameters. "fix" uses fixed ones calculated from the observed zero dose data or from a column named `pe` in `X`.

**Examples**

```r
 datatab<- read.table(system.file("doc", "expl1_cellsurvcurves.txt", package="CFAssay"), header=TRUE, sep="\t")
 names(datatab) #contains a column "cline"
 table(datatab$cline)
 fitcomp<- cellsurvLQdiff(datatab, curvevar="cline") #using default options
 print(fitcomp)
 plot(cellsurvLQfit(subset(datatab, cline=="okf6TERT1")), col=1)
 plot(cellsurvLQfit(subset(datatab, cline=="cal33"), col=2, add=TRUE)
 legend(0, 0.02, c("okf6TERT1", "cal33"), text.col=1:2)
 #using different options:
 print(cellsurvLQdiff(datatab, curvevar="cline", method="ls"))
 print(cellsurvLQdiff(datatab, curvevar="cline", PEmethod="fix"))
 print(cellsurvLQdiff(datatab, curvevar="cline", method="ls", PEmethod="fix"))
 print(cellsurvLQdiff(datatab, curvevar="cline", method="franken"))
```
Details

In the data frame X, Exp identifies the experimental replicates and may be numeric or non-numeric. method="ml" uses R function glm with quasipoisson family and link function "log". method="ls" uses R function lm. PEmethod="fit" fits plating efficiencies for every experiments. PEmethod="fix" uses observed plating efficiencies. If there is no 0-value in the dose-column, PEmethod is overwritten with "fix" and X has to contain a further column pe containing the plating efficiencies, i.e. ncolonies/ncells from untreated cells, not per hundred or percent.

Value

The function returns an object of class cellsurvLQfit, which is similar to classes glm or lm, however containing two additional entries, type and PEmethod, which are used for printing and plotting. The full result is returned invisibly, i.e. the function has to be used with print or plot or assigned to a variable, say for e.g. fit as in the example below.

print(cellsurvLQfit(X, method="franken"))

---

cfa2way Two-way analysis for cell survival data

Description

The function does an ANOVA of cell survival data from experimental 2-way designs where a treatment factor is tested on a control and on an altered cell line or where two different simultaneous treatments are tested on cells from a common unaltered clone. The function is a wrapper for the R-function glm. quasipoisson family is used with link function "log", i.e. dependency of treatment factors is considered as logarithmically additive.
Usage

cfa2way(X, A, B, param="A/B", method="ml")

Arguments

X  
a data frame which contains columns Exp, ncells, ncolonies and two further columns for the treatment variables, see details.

A  
a character string containing the name of a treatment or cell line variable (first factor in the model)

B  
a character string containing the name of a treatment or cell line variable (second factor in the model)

param  
Controls the parametrization of the model. Options are "A/B" for B nested in A , "B/A" for A nested in B and "A*B" for interaction term.

method  
determines the method used for the fit. "ml" is for maximum-likelihood, "ls" for least-squares.

Details

In the data frame X, Exp identifies the experimental replicates and may be numeric or non-numeric. The two treatment or cell line columns should have numeric values 0, 1, ... for 2, 3, ... levels. For e.g. if a column describes clonal alteration (transfection, knock-down etc.) by a gene then 0 means unaltered or control and 1 means altered. Similar if a column describes treatment with one dose then 0 means untreated and 1 treated. 2 would indicate another dose level from the same treatment drug without taking it as a continuous covariate as for cell survival curves for radiation.

Value

The function returns an object of class cfa2way containing three elements, fit1, fit2 and anv. fit1 and fit2 are objects of class glm when method="ml" or of class lm when method="ls". fit1 has logarithmic additive parameters without interaction. fit2 has logarithmic additive parameters and interaction. anv is of class anova and contains the F-test. The full result is returned invisibly, i.e. the function has to be used with print or assigned to a variable, say for e.g. fitcomp as in the example below.

Examples

datatab<- read.table(system.file("doc", "exp2_2waycfa.txt", package="CFAssay"), header=TRUE, sep="\t")
names(datatab) # has columns "x5fuCis" and "siRNA"
fitcomp<- cfa2way(datatab, A="siRNA", B="x5fuCis", param="A/B")
print(fitcomp, labels=c(A="siRNA",B="x5fuCis"))
print(cfa2way(datatab, A="siRNA", B="x5fuCis", param="A/B", method="ls"))
### pes

**Calculation of plating efficiencies from a curve data set containing one specified curve**

**Description**

The function calculates plating efficiencies, i.e. fractions of colonies per cell of untreated cells, for every experimental replicate in a data frame with one specified curve. For that, lines with zero dose \((dose = 0)\) are extracted from the data frame.

**Usage**

```r
pes(X)
```

**Arguments**

- `X` A data frame which contains columns `Exp`, `dose`, `ncells`, `ncolonies`.

**Details**

In the data frame `X`, `Exp` identifies the experimental replicates and may be numeric or non-numeric.

**Value**

The function returns a data frame with three columns `Exp`, `pe` and `S0`, containing experiment identifiers (biological replicates), measured plating efficiencies and plating efficiencies fitted separately for each repeated experiments. Rows of the data frame are named for the different experiments.

**Author(s)**

Herbert Braselmann

**Examples**

```r
datatab <- read.table(system.file("doc", "expl1_cellsurvcurves.txt", package="CFAssay"), header=TRUE, sep=\"\t\")
X <- subset(datatab, cline=="okf6TERT1")  #Specification of curve
pes(X)
pes(subset(datatab, cline=="cal33") )
```

### plot.cellsurvLQfit

**Plot of an LQ model fit**

**Description**

This function plots a cell survival curve derived from fitting an LQ model with function `cellsurvLQfit`.

**Usage**

```r
## S3 method for class 'cellsurvLQfit'
plot(x, xlim = NULL, ylim = c(0.008, 1), xlab = "Dose (Gy)", ylab = "Survival (1 = 100%)", col=1, pch=1)
```
plotExp

Arguments

x an object of class \texttt{cellsurvLQfit} resulting from function \texttt{cellsurvLQfit}.

\texttt{xlim} plot range for the x-axis. Default is the dose range of the data.

\texttt{ylim} plot range for the y-axis. Default is from 0.008 to 1.0

\texttt{xlab} label for the x-axis. Default is "Dose (Gy)".

\texttt{ylab} label for the y-axis. Default is "Survival (1 = 100\%)".

\texttt{col} colour for plot. Default is \texttt{col = 1}.

\texttt{pch} symbol for plotting points. Default is \texttt{pch = 1}.

\texttt{add} logical; if \texttt{TRUE} add to an already existing plot, see \texttt{curve}.

\texttt{...} further arguments to pass to R function \texttt{plot}.

cellsurvLQfit

tabExp

Examples

\begin{verbatim}
datatab<- read.table(system.file("doc", "expl1_cellsurvcurves.txt", package="CFAssay"), header=TRUE, sep="\t")
X<- subset(datatab, cline="okf6TERT1")
fit<- cellsurvLQfit(X)
plot(fit)
S0 <- pes(X)$S0
names(S0) <- pes(X)$S0
sfpmean(X, S0) #values of plotted mean survival fractions and error bars
# add second plot
plot(cellsurvLQfit(subset(datatab, cline="cal33")), col=2, add=TRUE)
\end{verbatim}

Description

Generic plotting of experimental repeats of cell survival data in separated plots. \texttt{plotExp} methods are defined for objects resulting from \texttt{CFAssay} functions \texttt{cellsurvLQfit} and \texttt{cfa2way}.

Usage

\texttt{plotExp(x, ...)}

Arguments

\texttt{x} should be an object of class \texttt{cellsurvLQfit} or \texttt{cfa2way}, see details.

\texttt{...} further arguments to pass to generic function \texttt{plotExp}, dependent of the class of the argument \texttt{x}. 
Details

For other objects than of class cellsurvLQfit or cfa2way, `plot.default` will be called. In this version of CFAssay this will give an error message and a hint to use one of the two defined classes.

`plotExp.cellsurvLQfit` and `plotExp.cfa2way`

Examples

```r
datatab<- read.table(system.file("doc", "expl1_cellsurvcurves.txt", package="CFAssay"), header=TRUE, sep="\t")
X<- subset(datatab, cline="okf6TERT1")
fit<- cellsurvLQfit(X)
#pdf("okf6TERT1_experimental_plots.pdf")
plotExp(fit)
#dev.off()
## Not run:
x <- 1
plotExp(X) #yields an error for this data type
## End(Not run)
```

`plotExp.cellsurvLQfit` Diagnostic plots of LQ model versus experiments

Description

This function plots the fit of an LQ model versus the fits of each experiment in a series of plots. It is recommended to direct it in a pdf-file.

Usage

```r
## S3 method for class 'cellsurvLQfit'
plotExp(x, xlim = NULL, ylim = c(0.001, 1.5), xlab = "Dose (Gy)", ylab = "Survival (1 = 100%)", ...)
```

Arguments

- `x` an object of class `cellsurvLQfit` resulting from function `cellsurvLQfit`.
- `xlim` range of x axis (dose).
- `ylim` range of y-axis.
- `xlab` label of x-axis.
- `ylab` label of y-axis.
- `...` further arguments to pass to generic function `plotExp`.

#pdf("TwoWay_experimental_plots.pdf")
plotExp(fitcomp, labels=c(A="siRNA", B="x5fuCis"))
dev.off()
plotExp.default

Default function for plotting of experimental repeats

Description

plotExp.default is the formal default method of the generic plotExp function.

Usage

## Default S3 method:
plotExp(x, ...)  

Arguments

x should be an object of class cellsurvLQfit or cfa2way, see details.

... further arguments to pass to generic function plotExp, dependent of the class of the argument x.

Details

In this version of CFAssay other objects than of class cellsurvLQfit or cfa2way this will give an error message and a hint to use one of the two defined classes.

fit<- cellsurvLQfit(X)
#pdf("okf6TERT1_experimental_plots.pdf")
  plotExp(fit)
#dev.off()
## Not run:
x <- 1
plotExp(X) #yields an error for this data type
## End(Not run)
### Print test results of comparison of two linear-quadratic cell survival curves

**Description**

The function prints linear coefficients alpha and dose-squared coefficients beta of calculated with function `cellsurvLQdiff`. In addition quality statistics of the fit and ANOVA F-test results for overall comparison of the coefficients are printed.

**Usage**

```R
## S3 method for class 'cellsurvLQdiff'
print(x, ...)
```

**Arguments**

- `x` an object of class `cellsurvLQdiff` resulting from function `cellsurvLQdiff`.
- `...` further arguments to pass to R function `print`.

**Author(s)**

Herbert Braselmann

**See Also**

**Examples**

```R
datatab<- read.table(system.file("doc", "expl1_cellsurvcurves.txt", package="CFAssay"), header=TRUE, sep="\t")
fitcomp<- cellsurvLQdiff(datatab, curvevar="cline") #using default options
print(fitcomp)
#using different options for cellsurvLQdiff:
print(cellsurvLQdiff(datatab, curvevar="cline", method="ls"))
print(cellsurvLQdiff(datatab, curvevar="cline", PEMethod="fix"))
print(cellsurvLQdiff(datatab, curvevar="cline", method="ls", PEMethod="fix"))
print(cellsurvLQdiff(datatab, curvevar="cline", method="franken"))
```

### Print summary of an LQ-model fit for cell survival data

**Description**

The function prints the results of an LQ-model fit for radiation dose dependent cell survival.

**Usage**

```R
## S3 method for class 'cellsurvLQfit'
print(x, ...)
```
Arguments

x an object of class `cellsurvLQfit` resulting from `cellsurvLQfit`.
...
  further arguments to pass to R function `print`.

Details

In this version of CFAssay the class argument x is checked by its entry `fit$type` and results in an error, when x results from an independent use of `glm` or `lm`.

fit<- cellsurvLQfit(X) #using default options
  print(fit)
  print(fit$type)
  print(fit$PEmethod)
#using other options
  print(cellsurvLQfit(X, method="ls"))
  print(cellsurvLQfit(X, PEmethod="fix"))
  print(cellsurvLQfit(X, method="ls", PEmethod="fix"))
  print(cellsurvLQfit(X, method="franken"))

print.cfa2way

Description

The function prints a summary of two-way analysis for cell survival data.

Usage

  ## S3 method for class 'cfa2way'
  print(x, labels=c("A","B"), ...)
sfpmean

See Also

cfa2way

Examples

datatab<- read.table(system.file("doc", "exp2_2waycfa.txt", package="CFAssay"), header=TRUE, sep="\t")
names(datatab) # has columns "x5fuCis" and "siRNA"
fitcomp<- cfa2way(datatab, A="siRNA", B="x5fuCis", param="A/B")
print(fitcomp, labels=c(A="siRNA",B="x5fuCis"))

sfpmean

Pointwise mean survival fractions for curves with several experimental replicates

Description

The function calculates mean survival fractions for curves averaged over experimental replicates. The function is employed by function plot.cellsurvLQfit for plotting observed means

Usage

sfpmean(X, S0=NULL)

Arguments

X  A data frame which contains columns Exp, dose, ncells, ncolonies and if S0=NULL, X has to contain a further column pe for plating efficiencies.

S0  If not NULL, a named numerical vector of length equal to the number of different experiments, i.e. length(S0)==length(unique(X$Exp)) has to be TRUE. Default is S0=NULL, i.e. undefined.

Details

In the data frame X, Exp identifies the experimental replicates and may be numeric or non-numeric. S0 may contain plating efficiencies for each replicate, resulting from function pes or from cellsurvLQfit (fitted). When S0=NULL, X must have a column with name pe, containing the plating efficiencies.

Value

A numerical matrix with two rows, the first row containing the survival fractions for each radiation dose, second row the standard deviations.
