Package ‘CountClust’

November 20, 2016

Type Package

Title Clustering and Visualizing RNA-Seq Expression Data using Grade of Membership Models

Version 1.1.4

Date 2016-11-05

Maintainer Kushal Dey <kkdey@uchicago.edu>

Description Fits grade of membership models (GoM, also known as admixture models) to cluster RNA-seq gene expression count data, identifies characteristic genes driving cluster memberships, and provides a visual summary of the cluster memberships.

Depends R (>= 3.3.0), ggplot2 (>= 2.1.0)

AbundanceGoM

GoM model fit for abundance data

Description

GoM model fit for abundance data

Usage

AbundanceGoM

Format

A list of GoM model output

Value

A list of GoM model output

BatchCorrectedCounts

Obtain Batch effect Corrected counts

Description

This function first converts counts data to log CPM data, then apply a linear model with the batch effect as a factor. We take the sum of intercept, residuals and mean batch effect across all the batches and then inverse transform it back to counts to get rid of batch effects.

Usage

BatchCorrectedCounts(data, batch_lab, use_parallel = TRUE)
Arguments

data       count matrix, with samples along the rows and features along the columns.
batch_lab  batch label vector.
use.parallel  if TRUE, we do a parallel analysis over features, else serial application.

Value

Returns a counts data, with same dimension as the input data, but which is corrected for batch_lab.

Examples

# Simulation example
N=500;
K=4;
G=100;
Label.Batch=c(rep(1,N/4),rep(2,N/4),rep(3,N/4),rep(4,N/4));
alpha_true=matrix(rnorm((K)*G,0.5,1),nrow=(K));
library(gtools)
tt <- 10;
omega_true = matrix(rbind(rdirichlet(tt*10,c(3,4,2,6)),
                          rdirichlet(tt*10,c(1,4,6,3)),
                          rdirichlet(tt*10,c(4,1,2,2)),
                          rdirichlet(tt*10,c(2,6,3,2)),
                          rdirichlet(tt*10,c(3,3,5,4))), nrow=N);
B=max(Label.Batch);
sigmab_true=2;
beta_true=matrix(0,B,G);
for(g in 1:G)
{
  beta_true[,g]=rnorm(B,mean=0,sd=sigmab_true);
}
read_counts=matrix(0,N,G);
for(n in 1:N){
  for(g in 1:G)
  {
    read_counts[n,g]=rpois(1, omega_true[n,]%*%exp(alpha_true[,g]
                            + beta_true[Label.Batch[n],g]));
  }
}
batchcorrect_counts <- BatchCorrectedCounts(read_counts, Label.Batch,
                                             use_parallel=FALSE)

Description

This function computes the center of gravity for each cluster by taking weighted mean of each component of features where the weights are determined from the theta matrix of the topic model fit.

cg_topics

Compute the center of gravity of the clusters
Usage

cg_topics(theta, feature.comp)

Arguments

theta The cluster probability distribution/theta matrix obtained from the GoM model fitting (it is a G x K matrix where G is number of features, K number of topics)

feature.comp the numeric matrix (G x L) comprising of values for each feature g and feature metadata l.

Value

Returns a matrix of cluster centers of gravity for the L feature metadata.

Examples

N=360;
M=560;
lat <- rep(1:N, M);
long <- rep(1:M, each=N)
comp <- cbind(lat, long);
data(AbundanceGoM)
center_gravity <- cg_topics(AbundanceGoM$theta, comp);

compare_omega

Re-ordering cluster membership proportion matrices and Information calculation

Description

This function computes a re-ordering of the clusters from GoM model fit in one model to make it comparable with that from another. The two models are applied on the same set of samples with same number of clusters, but the features may change from one model to another. The two models may not be of same type as well. One could be a DAPC model, the other a standard topic model. Aids in checking for consistency in topic proportion patterns across multiple GoM methods or across different types of feature sets.

Usage

compare_omega(omega1, omega2)

Arguments

omega1 cluster membership proportion matrix (N x K) from model 1

omega2 cluster membership proportion matrix (N x K) from model 2
**Value**

Returns a list containing

- `kl.dist` A symmetric KL divergence matrix across the re-ordered clusters of two omega matrices
- `kl.order_model2_topics` re-ordering of the clusters for omega2 to match the clusters for omega1 based on KL divergence
- `kl.information_content` A measure based on KL information to record how much information in omega2 is explained by omega1. Varies from 0 to 1
- `cor.dist` A correlation matrix across the re-ordered clusters of two omega matrices
- `cor.order_model2_topics` re-ordering of the clusters for omega2 to match the clusters for omega1 based on correlation information
- `cor.information_content` A measure based on correlation information to record how much information in omega2 is explained by omega1. Varies from 0 to 1

**Examples**

```r
tt=10;
omega1=matrix(rbind(gtools::rdirichlet(tt*10,c(3,4,2,6)),
gtools::rdirichlet(tt*10,c(1,4,6,3)),
gtools::rdirichlet(tt*10,c(4,1,2,2)))))
nrow=3*10*tt);
omega2=matrix(rbind(gtools::rdirichlet(tt*10,c(1,2,4,6)),
gtools::rdirichlet(tt*10,c(1,4,6,3)),
gtools::rdirichlet(tt*10,c(3,1,5,2))))
nrow=3*10*tt);
out <- compare_omega(omega1, omega2)
```

**compGoM**

compGoM: compare GoM model fits through log-likelihood, BIC and null loglikelihood

**Description**

This function takes the FitGoM output model fits and compute log likelihood, BIC and null model loglikelihood for the GoM models.

**Usage**

`compGoM(data, model_output)`

**Arguments**

- `data` matrix on which GoM model is fitted (samples along rows, genes along columns)
- `model_output` FitGoM output (a list).
Value

compGoM_models a vector of GoM model fit BIC, loglikelihood and null model loglikelihood for each model in FiGoM model input.

Examples

```r
read.data <- function() {
  x <- tempfile()
  download.file(paste0("https://cdn.rawgit.com/kkdey/",
                       "singleCellRNASeqMouseDeng2014",
                       "/master/data/Deng2014MouseEsc.rda"),
                 destfile = x, quiet = TRUE)
  z <- get(load(x))
  return(z)
}
Deng2014MouseESC <- read.data()

# Extract observed counts
deng.counts <- Biobase::exprs(Deng2014MouseESC)

# Import GoM fitting results
data("MouseDeng2014.FitGoM")
names(MouseDeng2014.FitGoM)
compGoM(data = t(deng.counts),
        model_output = MouseDeng2014.FitGoM)
```

Description

counts data for GTEx V6 Brain data for 200 genes

Usage

`ex.counts`

Format

A data frame 1259 by 200 in dimensions

Value

A data frame 1259 by 200 in dimensions
ExtractHighCorFeatures

Extracting most highly correlated genes with GoM topics/clusters

Description
This function compares grades of membership profile for each cluster in GoM model fit with the data expression profile to identify genes that are mostly strongly associated with each topic.

Usage
ExtractHighCorFeatures(omega, data, num_genes = 100)

Arguments
omega  
*omega* matrix, the relative grades of memberships from the GoM model fitting (a \( N \times K \) matrix where \( N \) is number of samples, \( K \) number of topics).

data  
\( G \times N \) matrix of the expression profile of genes across samples, where \( G \) is the number of features and \( N \) number of samples

num_genes  
The number of top associated genes with each cluster. Defaults to 100

Value
A list containing two items - a \( K \times num\_genes \) matrix of the top strongly associated/correlated indices/features for \( K \) clusters, and another \( K \times num\_genes \) matrix of the absolute values of the correlations.

Examples

```r
data("MouseDeng2014.FitGoM")
omega_mat <- MouseDeng2014.FitGoM$clust_6$omega;
read.data1 = function() {
  x = tempfile()
z = get(load((x)))
return(z)
}
Deng2014MouseESC <- read.data1()
deng.counts <- Biobase::exprs(Deng2014MouseESC)
out <- ExtractHighCorFeatures(omega_mat, deng.counts, num_genes=10)
```

ExtractTopFeatures

Extracting top driving genes driving GoM clusters

Description
This function uses relative gene expression profile of the GoM clusters and applies a KL-divergence based method to obtain a list of top features that drive each of the clusters.
Usage

ExtractTopFeatures(theta, top_features = 10, method = c("poisson", "bernoulli"), options = c("min", "max"))

Arguments

theta matrix, the relative gene expression profile of the GoM clusters (cluster probability distributions) from the GoM model fitting (a GxK matrix where G is number of features, K number of topics).

top_features The top features in each cluster k that are selected based on the feature’s ability to distinguish cluster k from cluster 1, . . . , K for all cluster k ≠ l. Default: 10.

method The underlying model assumed for KL divergence measurement. Two choices considered are "bernoulli" and "poisson". Default: poisson.

options if "min", for each cluster k, we select features that maximize the minimum KL divergence of cluster k against all other clusters for each feature. If "max", we select features that maximize the maximum KL divergence of cluster k against all other clusters for each feature.

Value

A matrix (K x top_features) which tabulates in k-th row the top feature indices driving the cluster k.

Examples

data("MouseDeng2014.FitGoM")
theta_mat <- MouseDeng2014.FitGoM$clust_6$theta;
top_features <- ExtractTopFeatures(theta_mat, top_features=100,
method="poisson", options="min");

FitGoM Grade of Membership (GoM) model fit!

Description

Fits a grade of membership model to count data. Default input includes a sample-by-feature matrix, the number of clusters (topics) to fit (K). The function is a wrapper of the topics() function implemented in Matt Taddy’s maptpx package.

Usage

FitGoM(data, K, tol = 0.1, path_rda = NULL, control = list())

Arguments

data counts data N x G, with N, the number of samples along the rows and G, number of genes along columns.

K the vector of clusters or topics to be fitted.
tol: Tolerance value for GoM model absolute log posterior increase at successive iterations (set to 0.1 as default).

path_rda: The directory path for saving the GoM model output. If NULL, it will return the output to console.

control: Control parameters. Same as topics() function of maptpx package.

Value

Saves the GoM model fit output for each cluster in vector K at the directory path in path_rda.

References

Examples

data("ex.counts")
out <- FitGoM(ex.counts, K=4, tol=100, control=list(tmax=100))
**handleNA**

Deal with NAs in the dataset!

**Description**

This function handles the NA values in the count data. If for a feature, the proportion of NAs is greater than threshold proportion, then we remove the feature, otherwise we use MAR substitution scheme using the distribution of the non NA values for the feature. If threshold proportion is 0, it implies removal of all features with NA values. Default value of threshold proportion is 0.

**Usage**

```r
handleNA(data, thresh_prop = 0)
```

**Arguments**

- `data`: count data in a sample by feature matrix.
- `thresh_prop`: threshold proportion of NAs for removal of feature or replacing the NA values.

**Details**

This function removes NAs from the counts data

**Value**

Returns a list with

- `data`: The modified data with NA substitution and removal
- `na_removed_cols`: The columns in the data with NAs that were removed
- `na_sub_cols`: The columns in the data with NAs that were substituted

**Examples**

```r
mat <- rbind(c(2,4,NA),c(4,7,8),c(3,NA,NA));
handleNA(mat,thresh_prop=0.5)
handleNA(mat)
```

---

**MouseDeng2014.FitGoM**

GoM model fit for Deng et al 2014 single cell RNA-seq data on mouse

**Description**

GoM model fit for Deng et al 2014 single cell RNA-seq data on mouse

**Usage**

```r
MouseDeng2014.FitGoM
```
Format

A list of GoM model output for 6 clusters (k=2:7)

Value

A list of GoM model output for 6 clusters (k=2:7)

nullmodel_GoM

Null models for Grade of Membership (GoM) cluster validation

Description

Use null models (popular in ecology) to generate randomized matrix of counts given the observed data matrix, fit the GoM model to these null matrices and compare the fit on null model data with that on the observed data. Used for validating the GoM clusters

Usage

nullmodel_GoM(counts, K, tol = 0.1, null.model = c("frequency", "richness", "independentswap", "trialswap"), iter_fill = 1000, iter_randomized = 100, plot = TRUE)
RemoveSparseFeatures

Removes features with a lot of 0 counts

Description

This function deals with zero counts in the counts dataset. If for a feature, the proportion of zeros across the samples is greater than filter_prop, then we remove the feature.

Usage

RemoveSparseFeatures(data, filter_prop = 0.9)

Arguments

data	count data in a sample by feature matrix.
filter_prop	threshold proportion. If the proportion of zeros for the feature exceeds this threshold then we remove the feature altogether. Default is 0.9.
Value

Returns a list with

data filtered data with sparse features removed
sparse_features the feature names of the features found sparse and removed

Examples

mat <- rbind(c(2,0,3,0,4),c(4,5,5,0,0),c(30,34,63,25,0),c(0,0,0,0,0));
RemoveSparseFeatures(mat, filter_prop = 0.5)
RemoveSparseFeatures(mat)

StructureGGplot

Structure plot using ggplot2

Description

Make the traditional Structure plot of GoM model with ggplot2

Usage

StructureGGplot(omega, annotation = NULL,
palette = RColorBrewer::brewer.pal(8, "Accent"), figure_title = "",
yaxis_label = "Tissue type", order_sample = TRUE,
sample_order_decreasing = TRUE, split_line = list(split_lwd = 1, split_col = "white"), plot_labels = TRUE, axis_tick = list(axis_ticks_length = 0.1,
axis_ticks_lwd_y = 0.1, axis_ticks_lwd_x = 0.1, axis_label_size = 3,
axis_label_face = "bold")

Arguments

omega Cluster membership probabilities of each sample. Usually a sample by cluster matrix in the Topic model output. The cluster weights sum to 1 for each sample.
annotation data.frame of two columns: sample_id and tissue_label. sample_id is a vetor consisting of character type of variable, which indicates the unique identifying number of each sample. tissue_label is a vector consisting of factor type of variable, which indicates the sample phenotype that is to be used in sorting and grouping the samples in the Structre plot; for example, tissue of origin in making Structure plot of the GTEx samples. Default is set to NULL for when no phenotype information is used to order the sample vectors.
palette Colors assigned to label the clusters. The first color in the palette is assigned to the cluster that is labeled 1 (usually arbitrarily assigned during the clustering process). Note: The number of colors must be the same or greater than the number of clusters. When the number of clusters is greater than the number of colors, the clusters that are not assigned a color are filled with white in the figure. The recommended choice of color palette is RColorBrewer, for instance RColorBrewer::brewer.pal(8, "Accent") or RColorBrewer::brewer.pal(9, "Set1").
figure_title Title of the plot.
yaxis_label  Axis label for the phenotype used to order the samples, for example, tissue type or cell type.

order_sample  Whether to order the samples that are of the same tissue label or phenotype label, that is, having the same label in the tissue_label variable. If TRUE, we order samples that are of the same phenotype label and sort the samples by membership of most representative cluster. If FALSE, we keep the order in the data.

sample_order_decreasing  If order_sample=TRUE, then order the sample in descending (TRUE) or ascending order.

split_line  Control parameters for the line that separates phenotype subgroups in the plot.

plot_labels  If TRUE, plot the axis labels.

axis_tick  Control parameters for x-axis and y-axis tick sizes.

Value

Plots the Structure plot visualization of the GoM model

Examples

# Example 1
data("MouseDeng2014.FitGoM")

# extract the omega matrix: membership weights of each cell
names(MouseDeng2014.FitGoM$clust_6)
omega <- MouseDeng2014.FitGoM$clust_6$omega

# make annotation matrix
annotation <- data.frame(sample_id = paste0("X", 1:NROW(omega)),
