Package ‘GenomicInteractions’

March 22, 2017

Type     Package
Title    R package for handling genomic interaction data
URL      https://github.com/ComputationalRegulatoryGenomicsICL/GenomicInteractions/
Version  1.8.1
Date     2015-07-20
Author   Harmston, N., Ing-Simmons, E., Perry, M., Baresic, A., Lenhard, B.
Maintainer Malcolm Perry <mgperry32@gmail.com>,
             Liz Ing-Simmons <liz.ing-simmons12@csc.mrc.ac.uk>
Imports  Rsamtools, rtracklayer, GenomicRanges, IRanges, BiocGenerics
         (>= 0.15.3), data.table, stringr, GenomeInfoDb, ggplot2, grid,
         gridExtra, methods, igraph, S4Vectors, dplyr, Gviz, Biobase,
         graphics, stats, utils
Suggests knitr, BiocStyle, testthat
VignetteBuilder knitr
Description R package for handling Genomic interaction data, such as
             ChIA-PET/Hi-C, annotating genomic features with interaction
             information and producing various plots / statistics.
biocViews  Software,Infrastructure,DataImport,DataRepresentation,HiC
License   GPL-3
Depends   R (>= 3.3), InteractionSet
RoxygenNote 5.0.1
NeedsCompilation no

GenomicInteractions-package

GenomicInteractions: A package for analysing chromosome conformation

Description

GenomicInteractions: A package for analysing chromosome conformation

Examples

library(GenomicInteractions)
**annotateAnchors**

*Annotate anchors - DEPRECATED*

**Description**

This function is deprecated and will be removed in the next release of Bioconductor. Use `annotateRegions` instead.

**Usage**

```r
annotateAnchors(GIObject, oneOrTwo, name, dat)
```

```r
## S4 method for signature 'GenomicInteractions,numeric,character,vector'
annotateAnchors(GIObject, oneOrTwo, name, dat)
```

**Arguments**

- **GIObject**: A GenomicInteractions object
- **oneOrTwo**: An integer indicating which anchor to annotate
- **name**: Character. Will be used as a column name for the elementMetadata of the annotated anchor.
- **dat**: Vector of the same length as the GenomicInteractions object, containing data with which to annotate the object.

**Value**

`invisible(1)`

---

**annotateInteractions**

*Annotate the interactions in a GInteractions object*

**Description**

This function will annotate both anchors with a list of named GRanges objects. Each metadata column is labeled "name.id" and contains the id of the genomic interval(s) it overlaps. Anonymous lists will be given names "FEATURE#.id" where # is the position in the list.

**Usage**

```r
annotateInteractions(GIObject, annotations)
```

```r
## S4 method for signature 'GInteractions,list'
annotateInteractions(GIObject, annotations)
```
## annotateRegions

**Annotate regions**

Use this function to add metadata parallel to the 'regions' slot of a GenomicInteractions or GInteractions object.

### Usage

```r
annotateRegions(GIObject, name, dat)
## S4 method for signature 'GInteractions,character,vector'
annotateRegions(GIObject, name, dat)
```

### Arguments

- **GIObject**
  A GenomicInteractions or GInteractions object

- **name**
  Character. Will be used as a column name.

- **dat**
  Vector of the same length as the GInteractions object, containing data with which to annotate the object.

### Value

```
invisible(1)
```

### Examples

```r
library("GenomicRanges")
data(hic_example_data)
data(mm9_refseq_promoters)
mm9_refseq_grl = split(mm9_refseq_promoters, mm9_refseq_promoters$id)
analyzeInteractions(hic_example_data, list(promoter=mm9_refseq_grl))
```
Examples

data(hic_example_data)
chip <- runif(n = length(regions(hic_example_data)), max = 1000)
nannotateRegions(hic_example_data, "chip", chip)

## S4 method for signature 'GInteractions'
asBED(x, keep.mcols = FALSE, score = "score")

Arguments

x        Generally, a tabular object to structure as BED
keep.mcols   logical whether to keep non-BED12 columns in final output (may cause prob-
problems with some parsers).
score    character, which field to export as "score" in BED12. Defaults to "auto" which
will choose score, then counts, if present, or fill column with zeros.
...

Value

A 'GRanges', with the metadata columns 'name', 'blockStarts' and 'blockSizes' added.

Examples

data(hic_example_data)
asBED(hic_example_data)
availableDisplayPars  The default display parameters for a track object class can be queries using the availableDisplayPars function.

Description
The default display parameters for a track object class can be queries using the availableDisplayPars function.

Usage
availableDisplayPars(class)

Arguments
class  A valid track object class name, or the object itself, in which case the class is derived directly from it.

This function provides the same functionality as Gviz::availableDisplayPars and allows the user to display the default display parameters for the InteractionTrack class. If the class of the track is not an InteractionTrack then the function calls the availableDisplayPars method in Gviz.

Value
returns a list of the default display parameters.

Examples
availableDisplayPars("InteractionTrack")

calculateDistances  Calculate interaction distances

Description
This function takes a GInteractions object and calculates the distances between the anchors according to the value of method. The distances returned follow the same convention as distance(x, y) in GenomicRanges where the distance between adjacent regions is 0. Note that if anchors are overlapping this method will print a warning and return the distance as 0.

Usage
calculateDistances(GIObject, method = "midpoint", floor = TRUE)

## S4 method for signature 'GInteractions'
calculateDistances(GIObject, method = "midpoint", floor = TRUE)
categoriseInteractions

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIObject</td>
<td>A GInteractions object</td>
</tr>
<tr>
<td>method</td>
<td>Character vector indicating how to calculate distances, must be one of 'midpoint', 'outer', 'inner'.</td>
</tr>
<tr>
<td>floor</td>
<td>A logical specifying whether to round down distances to nearest base pair or not. Default TRUE.</td>
</tr>
</tbody>
</table>

Value

An vector containing the distances between anchors/GRanges, NA if on different chromosomes, rounded down to the nearest bp.

Examples

```r
calculateDistances(test, method="midpoint")
```

categoriseInteractions

*Get the numbers of interaction types existing in your data*

Description

Get the numbers of interaction types existing in your data

Usage

categoriseInteractions(GIObject, node.classes = NULL, viewpoints = NULL)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIObject</td>
<td>A GInteractions object</td>
</tr>
<tr>
<td>node.classes</td>
<td>Optional. All node.classes to include in the analysis. Default: all node classes.</td>
</tr>
<tr>
<td>viewpoints</td>
<td>Optional. If set will only consider interactions where at least one anchor is of this node class. Default: all classes in node.classes.</td>
</tr>
</tbody>
</table>

Value

A data.frame.
Examples

```r
library("GenomicRanges")
data(hic_example_data)
data(mm9_refseq_promoters)
mm9_refseq_grl = split(mm9_refseq_promoters, mm9_refseq_promoters$id)
annotateInteractions(hic_example_data, list(promoter=mm9_refseq_grl))
categoriseInteractions(hic_example_data)
```

```
countsBetweenAnchors  Summarise interactions between defined anchors
```

Description

Calculate the number of paired-end reads mapping between a defined set of anchors. This function will ignore counts present in the input data.

Usage

```
countsBetweenAnchors(x, y, ...)  
```

```
## S4 method for signature 'GInteractions,GRanges'
countsBetweenAnchors(x, y,  
               ignore_overlaps = FALSE, ...)
```

Arguments

- `x` A GInteractions object
- `y` A GenomicRanges object
- `...` Extra parameters to pass to findOverlaps
- `ignore_overlaps` Allow overlapping anchors. Use this when you have overlapping anchors but be careful with multi-mapping. The "within" option can help with this.

Value

A GInteractions object with annotated counts between anchors

```
extport.bed12  Export interactions in BED12 format.
```

Description

Export interactions in BED12 format.

Usage

```
extport.bed12(GIObject, fn = NULL, score = "counts")  
```

```
## S4 method for signature 'GInteractions'
extport.bed12(GIObject, fn = NULL,  
               score = "counts")
```
export.bedpe

**Arguments**

- **GIObject**: A GInteractions object.
- **fn**: A filename to write the object to.
- **score**: Which metadata column to export as score.

Exports a GInteractions object to BED12 format, and writes to a specified file. If filename is not specified, then a data.frame containing the information is returned.

Bed12 files provide a method for visualising interactions, it is not a good format for storing all of the data associated with an interaction dataset, particularly for trans-chromosomal interactions, which can only be stored in the bed12 names field.

**Value**

invisible(1) if outputting to file or a data.frame containing all of the corresponding information

**Examples**

```r
data(hic_example_data)
export.bed12(hic_example_data, fn = tempfile(), score = "counts")
```

---

**export.bedpe**

Export interactions in BED Paired-End format.

**Description**

Exports a GInteractions object to BED-PE format, and writes to a specified file. If filename is not specified, then a data.frame containing the information is returned. The value of the score parameter defines which field is used to populate the score field.

**Usage**

```r
export.bedpe(GIObject, fn = NULL, score = "counts")
```

```r
## S4 method for signature 'GInteractions'
export.bedpe(GIObject, fn = NULL, score = "counts")
```

**Arguments**

- **GIObject**: A GInteractions object.
- **fn**: A filename to write the interactions data to.
- **score**: Which metadata column to use as score.

**Value**

invisible(1) if outputting to file or a data.frame containing all of the corresponding information

**Examples**

```r
data(hic_example_data)
export.bedpe(hic_example_data, fn = tempfile(), score = "counts")
```
export.chiasig  
Export interactions in a BEDPE-like format for use with ChiaSig

Description
Exports a GInteractions object to BEDPE like format, (anchor specifications and a column for reads connecting them) and writes to a specified file. If filename is not specified, then a data.frame containing the information is returned. The value of the score parameter defines which field is used to populate the score field.

Usage
export.chiasig(GIObject, fn = NULL, score = "counts")

## S4 method for signature 'GInteractions'
export.chiasig(GIObject, fn = NULL, score = "counts")

Arguments
GIObject  
a GInteractions object.

fn  
A filename to write the interactions data to

score  
Which metadata column to use as the score: counts or normalised

Value
invisible(1) if outputting to file or a data.frame containing all of the corresponding information

Examples
data(hic_example_data)
export.chiasig(hic_example_data, fn = tempfile(), score = "counts")

export.igraph  
Export interactions to an igraph object.

Description
Exports a GInteractions object to graph.data.frame for use by igraph package. This uses unique anchors as nodes and generates edges between them. For the resulting graph to be easily interpretable, anchors should be non-overlapping. This should already be the case for HiC data (either binned or restriction fragments), however ChIA-PET data can contain overlapping anchors, which may need to be reduced to non-overlapping regions before graph export.

Usage
export.igraph(GIObject)

## S4 method for signature 'GInteractions'
export.igraph(GIObject)
Arguments

GIObject: A GInteractions object.

Value

A graph.data.frame representation of the GInteractions object.

Examples

data(hic_example_data)
ig <- export.igraph(hic_example_data)

GenomicInteractions Function to create a GenomicInteractions object

Description

Create GenomicInteractions objects from two GRanges objects.

Usage

GenomicInteractions(anch01r1, anchor2, counts, ...)

## S4 method for signature 'GRanges,GRanges,numeric'
GenomicInteractions(anch01r1, anchor2, counts, ...)

## S4 method for signature 'GInteractions,ANY,ANY'
GenomicInteractions(anch01r1)

## S4 method for signature 'GInteractions,numeric,ANY'
GenomicInteractions(anch01r1, anchor2)

## S4 method for signature 'numeric,numerica,GRanges'
GenomicInteractions(anch01r1, anchor2, counts, ...)

## S4 method for signature 'GRanges,GRanges,GenomicRangesORmissing'
GenomicInteractions(anch01r1, anchor2, counts, ...)

## S4 method for signature 'missing,missing,GenomicRangesORmissing'
GenomicInteractions(anch01r1, anchor2, counts, ...)

## S4 method for signature 'ANY,ANY,ANY'
GenomicInteractions(anch01r1, anchor2, counts, ...)
Arguments

anchor1, anchor2

GRanges objects.

counts

An integer vector, defaults to 1.

... Additional data to be added to mcols

Value

a GenomicInteractions object

Examples

library(GenomicRanges)

anchor.one = GRanges(c("chr1", "chr1", "chr1", "chr1"), IRanges(c(10, 20, 30, 20), width=5))
anchor.two = GRanges(c("chr1", "chr1", "chr1", "chr2"), IRanges(c(100, 200, 300, 50), width=5))
interaction_counts = sample(1:10, 4)
test <- GenomicInteractions(anchor.one, anchor.two, counts=interaction_counts)
getters

Functions to access data held in a GenomicInteractions object.

Description

Use these functions to access data stored in each of the slots of a GenomicInteractions object.

Usage

name(GIObject)
anchorOne(GIObject)
anchorTwo(GIObject)
interactionCounts(GIObject)
annotationFeatures(GIObject)

## S4 method for signature 'GInteractions'
name(GIObject)

## S4 method for signature 'GInteractions'
description(object)

## S4 method for signature 'GInteractions'
anchorOne(GIObject)

## S4 method for signature 'GInteractions'
anchorTwo(GIObject)

## S4 method for signature 'GInteractions'
interactionCounts(GIObject)

## S4 method for signature 'GInteractions'
annotationFeatures(GIObject)

Arguments

GIObject A GInteractions object
object Object, possibly derived from class eSet-class.

Value

For 'anchorOne' and 'anchorTwo', a GRanges. For 'interactionCounts', a numeric vector with counts for each interaction in the object. For 'description' and 'name', a character vector with length 1. For 'annotationFeatures', a character vector of features with which the object was previously annotated, or 'NA' if the object is unannotated.
Examples

```r
library(GenomicRanges)

anchor.one = GRanges(c("chr1", "chr1", "chr1", "chr1"), IRanges(c(10, 20, 30, 20), width=5))
anchor.two = GRanges(c("chr1", "chr1", "chr1", "chr2"), IRanges(c(100, 200, 300, 50), width=5))
interaction.counts = sample(1:10, 4)
test <- GenomicInteractions(anchor.one, anchor.two, counts=interaction.counts)

name(test)
description(test)
anchorOne(test)
anchorTwo(test)
interactionCounts(test)
```

---

get_binom_ligation_threshold

get self ligation threshold with binomial test

Description

This function calculates a self ligation threshold according to a method based on that of Heidari et al., Genome Research, 2014. Briefly, paired reads are divided into in evenly spaced bins. For each bin, the number of reads that are aligned to opposite strand vs to the same strand is calculated. A binomial test is used to test if this is significantly different from the 50:50 ratio expected by chance if all reads are real interactions.

Usage

```r
get_binom_ligation_threshold(GIObject, max.distance = 20000, bin.size = 500,
p.cutoff = 0.05, adjust = "fdr", plot = TRUE)
```

Arguments

- **GIObject**: a GInteractions object of paired end reads
- **max.distance**: The maximum distance to consider between reads. Reads further apart than this distance should be very unlikely to be self ligations.
- **bin.size**: Bin size in base pairs.
- **p.cutoff**: P value cut off for a significant difference from 50:50. Default: 0.05
- **adjust**: Method to use to adjust p values. Default: fdr. See ‘help(p.adjust)’ for accepted values. Can also be NA for no adjustment.
- **plot**: TRUE by default. Whether to plot the percentage of reads on opposite strands vs difference and the binomial test p value vs distance.

Value

The cutoff in base pairs below which an interaction is likely to be a self ligation.
get_self_ligation_threshold

Get self ligation threshold with SD method from Heidari et al

Description

This function calculates a self ligation threshold according to the method published in Heidari et al., Genome Research, 2014. Briefly, paired reads are divided into evenly sized bins. For each bin, the log2 ratio of reads that are aligned to opposite strand vs to the same strand is calculated. Twice the standard deviation of this ratio at high distances is used as a cutoff to determine which bins are likely to contain mostly self-ligated reads.

Usage

get_self_ligation_threshold(GIObject, bins = 100, distance_th = 4e+05, plot = TRUE)

Arguments

GIObject: a GInteractions object of paired end reads
bins: Number of evenly sized bins to use.
distance_th: The threshold, in base pairs, to use as a cutoff to pick which bins to use to determine the standard deviation.
plot: TRUE by default. Whether to plot the log2 ratio of opposite to same strand reads vs distance.

Value

The cutoff in base pairs below which an interaction is likely to be a self ligation.

hg19.refseq.transcripts

Human Refseq transcripts from chr 17-18

Description

This dataset contains a subset of the transcripts from the Refseq annotation for mouse genome build hg19. See the ChIA-PET analysis vignette (vignettes(GenomicInteractions)) for more information on how this dataset was created.

Usage

data(hg19.refseq.transcripts)

Format

A GRanges object with length 2441.

Value

A GRanges object.
hic_example_data  Example HiC dataset

Description

This dataset contains HiC data from Seitan et al. 2013. The data was analysed using HOMER (Heinz et al. 2010) at a resolution of 100kb to find significant interactions. This example dataset has been filtered to retain only interactions on chromosomes 14 and 15 with a FDR < 0.1. The data has also been annotated for overlaps with Refseq promoters. See the HiC analysis vignette (vignettes(GenomicInteractions)) for more information on how this dataset was created.

Usage

data(hic_example_data)

Format

A GenomicInteractions object with length 8171.

Value

GenomicInteractions object

References

InteractionTrack  Constructor to create an InteractionTrack object

Description

Create InteractionTrack object from an GenomicInteractions object to visualise a specified chromosome.

Usage

InteractionTrack(x, chromosome = "", name = NULL, start = NULL, end = NULL)
**InteractionTrack-class**

A class to hold chromatin interaction data for a specific genomic region.

**Description**

@slot plottingFunction function @slot variables list @slot chromosome chromosome @slot stacking character

**Details**

InteractionTrack is a specific Gviz-derived class for enabling the visualisation of chromatin interaction data. The InteractionTrack class allows interactions on a specified chromosome to be visualised by examining interactions between anchors as bezier curves. The object is instantiated and used in a similar fashion to standard Gviz tracks and plotted using the `plotTracks` function.

Several additional display parameters (i.e. `displayPars(foo)=list(...)`) are defined for this class, including `plot.anchors` which can be used to specify whether anchors are to be drawn. `col.anchors.line` which can be used to alter the colour of border of these anchor elements and `col.anchors.fill` can be used to alter the fill colour of these elements. The value of `plot.outside` determines whether or not interactions which span outside of the window are to be plotted, and `col.outside` defines the colour of these interactions. Similarly `plot.trans` determines whether trans-interactions are plotted and `col.trans` specifies the colour of trans-interactions. By default,
the height of an arc representing an interaction is proportional to the number of reads/counts supporting that interaction. Instead of using the counts to define this, the height can be set to be proportional to either fdr or p.value using the interaction.measure display parameter. By changing the interaction.dimension to width, the line widths of each arc now represent the statistic supporting them. The heights of the arcs can be made to be proportional to log10 of the supporting statistic by changing interaction.dimension.transform to log. col.interactions sets the colour of arcs representing interactions within the region of interest. It is possible to colour the arcs by the type of interaction they are involved in (i.e. promoter-promoter interactions etc) by setting the col.interactions.types display parameter to be a named vector of colours, where the name corresponds to the type of interaction. This is applicable to anchors regions through the use of the col.anchors.line.node.class and col.anchors.fill.node.class parameters.

---

**is.pp**  
*Interaction Type Helpers*

### Description

Functions to classify interactions within GInteractions objects.

- "isInteractionType" takes two character arguments which are annotated node classes and returns interactions between them.
- "is.pp", "is.pd" etc. are bindings for common annotations:
  - p promoter
  - d distal
  - t terminator
- "is.trans" & "is.cis" select trans-chromosomal and intra-chromosomal interactions, respectively

### Usage

```r
is.pp(GIObject)
is.pd(GIObject)
is.pt(GIObject)
is.dd(GIObject)
is.dt(GIObject)
is.tt(GIObject)
isInterationType(GIObject, x, y)
is.trans(GIObject)
is.cis(GIObject)
```

## S4 method for signature 'GInteractions'

is.pp(GIObject)
makeGenomicInteractionsFromFile

Function to create GenomicInteraction objects from a file

Description

Function to create GenomicInteraction objects from a variety of files. The resulting objects contain information on which genomic regions are interacting with each other, and the number of counts supporting each interaction. It is also possible to store information on associated p-values and false-discovery rates (FDR). It is possible to create GenomicInteractions objects for various datasets.
including Hi-C and ChIA-PET. It is possible to read interactions from a variety of files including BAM files, bed files (BED12 and BEDPE) and from the output from standard processing pipelines, such as HOMER and ChIA-PET tool. GenomicInteractions objects can also be created using calls of the form `new("GenomicInteractions", ...)`. For hiclib, it expects the directory in which the files extracted using h5dictToTxt.py from the hdf5 file are located, where as for all of the other file types it expects the full filename. Note that recent versions of hiclib (2015-) cannot export the required data and so this function will only work with older files.

**Usage**

```r
makeGenomicInteractionsFromFile(fn, type, experiment_name = "", description = "", chr_names = NULL)
```

**Arguments**

- `fn` Filename or, if type="hiclib", folder
- `type` One of "chiapet.tool", "bed12", "bedpe", "hiclib", "homer", "bam", "two.bams".
- `experiment_name` Experiment name.
- `description` Description of experiment.
- `chr_names` a vector of chromosome names in order, required for re-naming chromosomes for hiclib import

**Value**

a GenomicInteractions object

**Examples**

```r
k562.rep1 <- makeGenomicInteractionsFromFile(
  system.file(package="GenomicInteractions", "extdata", "k562.rep1.cluster.pet3+.txt"),
  type="chiapet.tool", experiment_name="k562", description="k562 pol2 8wg16")

k562.rep1
```

---

**mm9_refseq_promoters**  
**Mouse Refseq promoters from chr 14-15**

**Description**

This dataset contains a subset of the promoters from the Refseq annotation for mouse genome build mm9. See the HiC analysis vignette (vignettes(GenomicInteractions)) for more information on how this dataset was created.

**Usage**

```r
data(mm9_refseq_promoters)
```
$plotAvgViewpoint$

**Format**

A GRanges object with length 2441.

**Value**

A GRanges object.

$\text{plotAvgViewpoint}$  $\text{Plot coverage around a set of virtual 4C viewpoints}$

**Description**

Plots summarised coverage of interactions around a set of viewpoints, e.g. promoters. This function requires the output of `$\text{viewPoint()}$` as input.

**Usage**

\[
\text{plotAvgViewpoint}(x, \text{left_dist} = 1e+05, \text{right_dist} = 1e+05, \\
ylab = "Average signal", xlab = "Relative position", fix = "center", \\
\ldots)
\]

**Arguments**

- `x` A GInteractions object which is output from viewPoint
- `left_dist` Distance 'left' of interactions to consider, in bp.
- `right_dist` Distance 'right' of interactions to consider, in bp.
- `ylab` Y axis label.
- `xlab` X axis label.
- `fix` One of "center", "start", "end". Passed to 'resize'. Interaction distances are calculated relative to this part of the bait.
- `\ldots` additional arguments to plot

**Value**

Coverage that is plotted (invisibly)

**Examples**

```r
data(hic_example_data)
library(GenomicRanges)
pos <- GRanges(seqnames="chr15", ranges=IRanges(start=59477709, end=59482708))
region <- GRanges(seqnames="chr15", ranges=IRanges(start=58980209, end=59980208))
vp <- viewPoint(hic_example_data, pos, region)
plotAvgViewpoint(vp, left_dist = 1000000, right_dist = 100000)
```
plotCounts

plotCisTrans

Plots the percentages of cis and trans interactions for a GInteractions object as a donut plot.

Description

Plots the percentages of cis and trans interactions for a GInteractions object as a donut plot.

Usage

plotCisTrans(GIObject)

Arguments

GIObject
A GInteractions object

Value

A ggplot2 plot

Examples

data(hic_example_data)
plotCisTrans(hic_example_data)

plotCounts

Plot a bar chart of the number of interactions supported by different numbers of reads in your data.

Description

Plot a bar chart of the number of interactions supported by different numbers of reads in your data.

Usage

plotCounts(GIObject, normalise = FALSE, cut = 10)

Arguments

GIObject
A GInteractions object.

normalise
Logical. If TRUE, plots proportion of total reads instead of count.

cut
Numeric, can be NULL. Default: 10. All interactions with counts > cut are consolidated into a single category.

Value

A ggplot2 plot
plotDists

Examples

data(hic_example_data)
plotCounts(hic_example_data)
plotCounts(hic_example_data, normalise=TRUE)

Description

Plots a histogram of interaction distances for a GInteractions Object

Usage

plotDists(GIObject, breaks = c(0, 1000, 5000, 10000, 50000, 1e+05, 5e+05,
1e+06, 2e+06), method = "midpoint")

Arguments

GIObject A GInteractions object
breaks A numeric vector of breaks for the histogram
method Method used for distance between anchors. Passed to calculateDistances. One
of "midpoint", "inner", or "outer".

Value

A ggplot2 plot

Examples

data(hic_example_data)
plotDists(hic_example_data)

plotInteractionAnnotations

Plot a donut plot of interaction types for an annotated GInteractions object

Description

Plot a donut plot of interaction types for an annotated GInteractions object

Usage

plotInteractionAnnotations(GIObject, node.classes = NULL, viewpoints = NULL,
other = 0, keep.order = FALSE, legend = FALSE)
plotSummaryStats

Arguments

GIObject  A GInteractions object
node.classes Optional. All node.classes to include in the analysis. Default: all node classes.
viewpoints Optional. If set will only consider interactions where at least one anchor is of
this node class. Default: all classes in node.classes.
other Optional. Interaction types making up fewer than "other" percent of the total
interactions will be consolidated into a single "other" category.
keep.order Optional. Logical. Keep original order of node.classes for plotting or not. De-
fault: FALSE, alphabetical order.
legend Optional. Logical. If TRUE, legend is plotted to right of donut plot. If FALSE,
donut plot is annotated with category names.

Value

A ggplot2 plot

Examples

library("GenomicRanges")
data(hic_example_data)
data(mm9_refseq_promoters)
mm9_refseq_grl = split(mm9_refseq_promoters, mm9_refseq_promoters$id)
annotateInteractions(hic_example_data, list(promoter=mm9_refseq_grl))
plotInteractionAnnotations(hic_example_data)

plotSummaryStats  Plot summary statistics for a GInteractions object

Description

Makes summary plots of the counts, interaction distances, interaction annotations, and percentage of
cis and trans interactions for a GInteractions object using 'plotCounts', 'plotDists', 'plotCisTrans',
and 'plotInteractionAnnotations'.

Usage

plotSummaryStats(GIObject, other = 5, cut = 10)

Arguments

GIObject  A GInteractions object
other Default 5. Passed to plotInteractionAnnotations. Interaction types making up
fewer than "other" percent of the total interactions will be consolidated into a
single "other" category.
cut Default 10. Passed to plotCounts. All interactions with counts > cut are consoli-
dated into a single category.

Value

invisible(1)
Examples

```r
data(hic_example_data)
plotSummaryStats(hic_example_data)
```

---

**plotViewpoint**

*Plot coverage around a virtual 4C viewpoint*

**Description**

Plots coverage of interactions around a given viewpoint. This function requires the output of `viewPoint()` as input. You should additionally specify the total region you wish to plot.

**Usage**

```r
plotViewpoint(x, region, ylab = "Signal", xlab = NULL, ...)
```

**Arguments**

- **x**
  - a GIInteractions object which is output from `viewPoint`
- **region**
  - The genomic region to plot
- **ylab**
  - Y axis label.
- **xlab**
  - X axis label. By default this is the chromosome of the region that is being plotted.
- **...**
  - additional arguments to plot

**Value**

Coverage that is plotted (invisibly)

**Examples**

```r
data(hic_example_data)
library(GenomicRanges)
pos <- GRanges(seqnames="chr15", ranges=IRanges(start=59477709, end=59482708))
region <- GRanges(seqnames="chr15", ranges=IRanges(start=58980209, end=59980208))
vp <- viewPoint(hic_example_data, pos, region)
plotViewpoint(vp, region)
```
removeDups

Remove all but one occurrence of a duplicated interaction

Description

Removes all but the first occurrence of a duplicated interaction (defined as having identical coordinates for both anchors). N.B. this does not summarise the total counts of all the duplicates. It is designed for removing potential PCR duplicates after reading in .bam files.

Usage

removeDups(GIObject)

Arguments

GIObject A GInteractions object.

Value

A GInteractions object that is a subset of the input object.

resetAnnotations

Reset annotations made to a GInteractions object

Description

This function removes all annotations from a GInteractions object by deleting all of the metadata columns associated with both anchors.

Usage

resetAnnotations(GIObject)

## S4 method for signature 'GInteractions'
resetAnnotations(GIObject)

Arguments

GIObject An annotated GInteractions object

Value

invisible(1)

Examples

data(hic_example_data)
resetAnnotations(hic_example_data)
sameStrand

Tests whether anchors have the same strand.

Description

This is designed for processing .bam files.

Usage

sameStrand(GIObject)

Arguments

GIObject A GInteractions object

Value

A logical vector denoting with TRUE if both anchors of an interaction are on the same strand and FALSE otherwise.

setters

Functions to set data held in a GInteractions object.

Description

Use these functions to set data stored in each of the slots of a GInteractions object.

Usage

name(GIObject) <- value
interactionCounts(GIObject) <- value

## S4 replacement method for signature 'GInteractions'
name(GIObject) <- value

## S4 replacement method for signature 'GInteractions,ANY'
description(object) <- value

## S4 replacement method for signature 'GInteractions'
interactionCounts(GIObject) <- value

Arguments

GIObject A GenomicInteractions object
value A vector to replace a slot in the object
object Object, possibly derived from class eSet-class.
Value

GenomicInteractions object

Examples

library(GenomicRanges)

anchor.one = GRanges(c("chr1", "chr1", "chr1", "chr1"), IRanges(c(10, 20, 30, 20), width=5))
anchor.two = GRanges(c("chr1", "chr1", "chr1", "chr2"), IRanges(c(100, 200, 300, 50), width=5))
interaction_counts = sample(1:10, 4)
test <- GenomicInteractions(anchor.one, anchor.two, experiment_name="test",
                           description="this is a test", counts=interaction_counts)

name(test) <- "Mouse test"
name(test)

description(test) <- "This is a test using the mouse genome"
description(test)

interactionCounts(test) <- c(2,3,8,5)
interactionCounts(test)

subsetByFeatures

Subset a GInteractions object by features

Description

Subsets interactions for which at least one of the anchors overlaps with a given GRanges object. Alternatively, subsets interactions based on annotated feature IDs for a particular feature.

Usage

subsetByFeatures(GIObject, features, feature.class = NULL)

## S4 method for signature 'GInteractions,GRanges,missing'
subsetByFeatures(GIObject, features, 
                feature.class = NULL)

## S4 method for signature 'GInteractions,GRangesList,missing'
subsetByFeatures(GIObject, features, 
                 feature.class = NULL)

## S4 method for signature 'GInteractions,character,character'
subsetByFeatures(GIObject, 
                 features, feature.class = NULL)

Arguments

GIObject  A GInteractions object
sum,GInteractions-method

Return the total number of interactions in a GInteractions GIObject

Description

Return the total number of interactions in a GInteractions GIObject

Usage

## S4 method for signature 'GInteractions'
sum(x)

Arguments

x  
GInteractions GIObject

Value

The sum of the counts in GIObject

summariseByFeaturePairs

Summarise the number of interactions between two sets of features.

Description

This function will calculate the number of observed interactions between two sets of features
provided by the end-user. This allows the summarisation of the number of features of a specific type
a particular region is involved in and how many interactions exist between them.
Usage

summariseByFeaturePairs(GIObject, features.one, feature.name.one, features.two, feature.name.two)

## S4 method for signature 'GInteractions'
summariseByFeaturePairs(GIObject, features.one, feature.name.one, features.two, feature.name.two)

Arguments

- **GIObject**: An annotated GInteractions object
- **features.one**: A GRanges object containing the feature set of interest
- **feature.name.one**: The name of the first feature set of interest
- **features.two**: A GRanges object containing the second feature set of interest
- **feature.name.two**: The name of the second feature set of interest

Value

A data frame with one line for each range in 'features'

Examples

```r
data("hic_example_data")
data("mm9_refseq_promoters")
data("thymus_enhancers")
annotateInteractions(hic_example_data, list(promoter = mm9_refseq_promoters, enhancer = thymus_enh))
# can be slow so subset of features used for examples
p <- unique(unlist(head(regions(hic_example_data)$promoter.id)))
e <- unique(unlist(head(regions(hic_example_data)$enhancer.id)))
p <- p[!is.na(p)]
e <- mm9_refseq_promoters[p]
e <- e[!is.na(e)]
e <- thymus_enh[e]
ep_summary <- summariseByFeaturePairs(hic_example_data, p, "promoter", e, "enhancer")
```

summariseFeatures  
*Summary statistics of interactions for a given feature set*

Description

This function will calculate summary statistics for each element in the given feature set, including the number of interactions (the sum of all interaction counts), number of unique interactions and number of trans- (interchromosomal) interactions. It also returns some statistics for the distances of interactions for all interactions of the feature, and for the different interaction types e.g. promoter-distal.
Usage

```r
summariseByFeatures(GIObject, features, feature.name, 
    distance.method = "midpoint", annotate.self = FALSE)
```

## S4 method for signature 'GInteractions'

```r
summariseByFeatures(GIObject, features, feature.name, 
    distance.method = "midpoint", annotate.self = FALSE)
```

Arguments

- **GIObject**: An annotated GInteractions object
- **features**: A GRanges object containing the feature set
- **feature.name**: The name of the feature set
- **distance.method**: Method for calculating distances between anchors, see ?calculateDistances
- **annotate.self**: Logical. Indicates whether to annotate self interactions, i.e. where a feature in ‘features’ overlaps both anchors of an interaction. Default: FALSE.

Value

A data frame with one line for each range in ‘features’

Examples

```r
data("hic_example_data")
data("mm9_refseq_promoters")
annotateInteractions(hic_example_data, list(promoter = mm9_refseq_promoters))
summariseByFeatures(hic_example_data, mm9_refseq_promoters[1:10], "promoter")
```

---

**thymus_enh**

*Putative enhancers from mouse thymus data*

Description

This dataset contains a set of mouse thymus enhancers derived from ChIP-seq data from mouse thymus, as described in Shen et al. 2012. See the HiC analysis vignette for more details. (`vignettes(GenomicInteractions)`).

Usage

```r
data("thymus_enhancers")
```

Format

A GRanges object

Value

A GRanges object

References

updateObject, GenomicInteractions-method

updateObject method for GenomicInteractions 1.3.7 and earlier

Description
updateObject method for GenomicInteractions 1.3.7 and earlier

Usage
## S4 method for signature 'GenomicInteractions'
updateObject(object, ..., verbose = FALSE)

Arguments
object Object to be updated for updateObject and updateObjectFromSlots. Object for slot information to be extracted from for getObjectSlots.
...
Additional arguments, for use in specific updateObject methods.
verbose TRUE or FALSE, indicating whether information about the update should be reported. Use message to report this information.

Value
A GenomicInteractions object

viewPoint

Virtual 4C viewpoint

Description
This function creates a GInteractions object representing interactions originating at a given viewpoint ("bait"), or set of viewpoints. This is similar to the idea of a virtual 4C experiment where you are interested in interactions with a specific region.

Usage
viewPoint(x, bait, region = NULL, ...)

Arguments
x A GInteractions object.
bait A GRanges object describing bait regions.
region If present, a GRanges object specifying the region to look for bait interactions in.
...
additional arguments to findoverlaps
**Details**

The object returned has the "bait" as anchor one, and the interacting regions as anchor two. By default this is genome wide. If you only want to consider interactions within a certain distance around the bait, you can specify a region to consider.

Multiple baits can be given, e.g. to find all interactions around promoters.

You may want to visualise the resulting interactions in a genome browser - you can do this by creating coverage over anchor two of the object and exporting as a wig or bedgraph file.

**Value**

A GInteractions object.

**Examples**

```r
data(hic_example_data)
library(GenomicRanges)
pos <- GRanges(seqnames="chr15", ranges=IRanges(start=59477709, end=59482708))
region <- GRanges(seqnames="chr15", ranges=IRanges(start=58980209, end=59980208))
vp <- viewPoint(hic_example_data, pos, region)
```
