Package ‘GenomicRanges’

March 22, 2017

Title  Representation and manipulation of genomic intervals and variables defined along a genome

Description  The ability to efficiently represent and manipulate genomic annotations and alignments is playing a central role when it comes to analyzing high-throughput sequencing data (a.k.a. NGS data).

The GenomicRanges package defines general purpose containers for storing and manipulating genomic intervals and variables defined along a genome. More specialized containers for representing and manipulating short alignments against a reference genome, or a matrix-like summarization of an experiment, are defined in the GenomicAlignments and SummarizedExperiment packages respectively. Both packages build on top of the GenomicRanges infrastructure.

Version  1.26.4

Encoding  UTF-8

Author  P. Aboyoun, H. Pagès, and M. Lawrence

Maintainer  Bioconductor Package Maintainer <maintainer@bioconductor.org>

biocViews  Genetics, Infrastructure, Sequencing, Annotation, Coverage, GenomeAnnotation

Depends  R (>= 2.10), methods, stats4, BiocGenerics (>= 0.17.5), S4Vectors (>= 0.9.47), IRanges (>= 2.7.8), GenomeInfoDb (>= 1.1.20)

absoluteRanges

Transform genomic ranges into "absolute" ranges

**Description**

absoluteRanges transforms the genomic ranges in \(x\) into absolute ranges i.e. into ranges counted from the beginning of the virtual sequence obtained by concatenating all the sequences in the underlying genome (in the order reported by `seqlevels(x)`).

`relativeRanges` performs the reverse transformation.

NOTE: These functions only work on small genomes. See Details section below.
absoluteRanges

Usage

absoluteRanges(x)
relativeRanges(x, seqlengths)

## Related utility:
isSmallGenome(seqlengths)

Arguments

x
For absoluteRanges: a GenomicRanges object with ranges defined on a small
genome (see Details section below).
For relativeRanges: a Ranges object.

seqlengths
An object holding sequence lengths. This can be a named integer (or numeric)
vector with no duplicated names as returned by seqlengths(), or any object
from which sequence lengths can be extracted with seqlengths().
For relativeRanges, seqlengths must describe a small genome (see Details
section below).

Details

Because absoluteRanges returns the absolute ranges in an IRanges object, and because an IRanges
object cannot hold ranges with an end > .Machine$integer.max (i.e. >= 2^31 on most plat-
forms), absoluteRanges cannot be used if the size of the underlying genome (i.e. the total length
of the sequences in it) is > .Machine$integer.max. Utility function isSmallGenome is pro-
vided as a mean for the user to check upfront whether the genome is small (i.e. its size is <=
.Machine$integer.max) or not, and thus compatible with absoluteRanges or not.
relativeRanges applies the same restriction by looking at the seqlengths argument.

Value

An IRanges object for absoluteRanges.
A GRanges object for relativeRanges.
absoluteRanges and relativeRanges both return an object that is parallel to the input object (i.e.
same length and names).
isSmallGenome returns TRUE if the total length of the underlying sequences is <= .Machine$integer.max
(e.g. Fly genome), FALSE if not (e.g. Human genome), or NA if it cannot be computed (because
some sequence lengths are NA).

### Examples

```r
## ---------------------------------------------------------------------
## TOY EXAMPLE
## ---------------------------------------------------------------------

gr <- GRanges(Rle(c("chr2", "chr1", "chr3", "chr1"), 4:1),
               IRanges(1:10, width=5),
               seqinfo=Seqinfo(c("chr1", "chr2", "chr3"), c(100, 50, 20)))

ar <- absoluteRanges(gr)
ar

gr2 <- relativeRanges(ar, seqlengths(gr))
gr2

## Sanity check:
stopifnot(all(gr == gr2))

## ---------------------------------------------------------------------
## ON REAL DATA
## ---------------------------------------------------------------------

## With a "small" genome

library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
ex <- exons(txdb)
ex

isSmallGenome(ex)

## Note that because isSmallGenome() can return NA (see Value section above),
## its result should always be wrapped inside isTRUE() when used in an if statement:

if (isTRUE(isSmallGenome(ex))) {
  ar <- absoluteRanges(ex)
  ar

  ex2 <- relativeRanges(ar, seqlengths(ex))
  ex2  # original strand is not restored

  ## Sanity check:
  strand(ex2) <- strand(ex)  # restore the strand
  stopifnot(all(ex == ex2))
}

## With a "big" genome (but we can reduce it)

library(TxDb.Hsapiens.UCSC.hg19.knownGene)
txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
ex <- exons(txdb)
isSmallGenome(ex)

## Not run:
  absoluteRanges(ex)  # error!

## End(Not run)
```
## Constraints

### Enforcing constraints thru Constraint objects

#### Description

Attaching a Constraint object to an object of class A (the "constrained" object) is meant to be a convenient/reusable/extensible way to enforce a particular set of constraints on particular instances of A.

**THIS IS AN EXPERIMENTAL FEATURE AND STILL VERY MUCH A WORK-IN-PROGRESS!**

#### Details

For the developer, using constraints is an alternative to the more traditional approach that consists in creating subclasses of A and implementing specific validity methods for each of them. However, using constraints offers the following advantages over the traditional approach:

- The traditional approach often tends to lead to a proliferation of subclasses of A.
- Constraints can easily be re-used across different classes without the need to create any new class.
- Constraints can easily be combined.

All constraints are implemented as concrete subclasses of the Constraint class, which is a virtual class with no slots. Like the Constraint virtual class itself, concrete Constraint subclasses cannot have slots.

Here are the 7 steps typically involved in the process of putting constraints on objects of class A:

1. Add a slot named `constraint` to the definition of class A. The type of this slot must be `ConstraintORNULL`. Note that any subclass of A will inherit this slot.

2. Implements the `constraint()` accessors (getter and setter) for objects of class A. This is done by implementing the "constraint" method (getter) and replacement method (setter) for objects of class A (see the examples below). As a convenience to the user, the setter should also accept the name of a constraint (i.e. the name of its class) in addition to an instance of that class. Note that those accessors will work on instances of any subclass of A.

3. Modify the validity method for class A so it also returns the result of `checkConstraint(x, constraint(x))` (append this result to the result returned by the validity method).

4. Testing: Create `x`, an instance of class A (or subclass of A). By default there is no constraint on it (`constraint(x)` is NULL). `validObject(x)` should return TRUE.

### Constraints

```r
## However, if we are only interested in some chromosomes, we might
## still be able to use absoluteRanges():
seqlevels(ex, force=TRUE) <- paste0("chr", 1:10)
isSmallGenome(ex) # TRUE!
ar <- absoluteRanges(ex)
ex2 <- relativeRanges(ar, seqlengths(ex))

## Sanity check:
strand(ex2) <- strand(ex)
stopifnot(all(ex == ex2))
```
5. Create a new constraint (MyConstraint) by extending the Constraint class, typically with 
setClass("MyConstraint", contains="Constraint"). This constraint is not enforcing 
anything yet so you could put it on x (with constraint(x) <- "MyConstraint"), but not 
much would happen. In order to actually enforce something, a “checkConstraint” method 
for signature c(x="A", constraint="MyConstraint") needs to be implemented.

6. Implement a “checkConstraint” method for signature c(x="A", constraint="MyConstraint"). 
Like validity methods, “checkConstraint” methods must return NULL or a character vector 
describing the problems found. Like validity methods, they should never fail (i.e. they should 
ever raise an error). Note that, alternatively, an existing constraint (e.g. SomeConstraint) 
can be adapted to work on objects of class A by just defining a new “checkConstraint” 
method for signature c(x="A", constraint="SomeConstraint"). Also, stricter constraints 
can be built on top of existing constraints by extending one or more existing constraints (see 
the examples below).

7. Testing: Try constraint(x) <- "MyConstraint". It will or will not work depending on 
whether x satisfies the constraint or not. In the former case, trying to modify x in a way that 
breaks the constraint on it will also raise an error.

Note

WARNING: This note is not true anymore as the constraint slot has been temporarily removed 
from GenomicRanges objects (starting with package GenomicRanges >= 1.7.9).
Currently, only GenomicRanges objects can be constrained, that is:

• they have a constraint slot;
• they have constraint() accessors (getter and setter) for this slot;
• their validity method has been modified so it also returns the result of checkConstraint(x, constraint(x)).

More classes in the GenomicRanges and IRanges packages will support constraints in the near 
future.

setClass, is, setMethod, showMethods, validObject, GenomicRanges-class

Examples

## The examples below show how to define and set constraints on 
## GenomicRanges objects. Note that this is how the constraint() 
## setter is defined for GenomicRanges objects:
#setReplaceMethod("constraint", "GenomicRanges", 
# function(x, value) 
# { 
#   if (isSingleString(value)) 
#     value <- new(value) 
#   if (!is(value, "ConstraintORNULL")) 
#     stop("the supplied 'constraint' must be a ", 
#       "Constraint object, a single string, or NULL") 
#   x@constraint <- value 
#   validObject(x) 
#   x 

We'll use the GRanges instance 'gr' created in the GRanges examples to test our constraints:

```r
echo=FALSE
#constraint(gr)
```

---

**EXAMPLE 1: The HasRangeTypeCol constraint.**

The HasRangeTypeCol constraint checks that the constrained object has a unique "rangeType" metadata column and that this column is a 'factor' Rle with no NAs and with the following levels (in this order): gene, transcript, exon, cds, 5utr, 3utr.

```r
setClass("HasRangeTypeCol", contains="Constraint")

Like validity methods, "checkConstraint" methods must return NULL or a character vector describing the problems found. They should never fail i.e. they should never raise an error.

```r
setMethod("checkConstraint", c("GenomicRanges", "HasRangeTypeCol"),
function(x, constraint, verbose=FALSE)
{
  x_mcols <- mcols(x)
  idx <- match("rangeType", colnames(x_mcols))
  if (length(idx) != 1L || is.na(idx)) {
    msg <- c("mcols(x) must have exactly 1 column ",
             "named "rangeType\"")
    return(paste(msg, collapse=""))
  }
  rangeType <- x_mcols[[idx]]
  .LEVELS <- c("gene", "transcript", "exon", "cds", "5utr", "3utr")
  if (!is(rangeType, "Rle") ||
      S4Vectors:::anyMissing(runValue(rangeType)) ||
      !identical(levels(rangeType), .LEVELS))
  { msg <- c("mcols(x)$rangeType must be a ",
             "'factor' Rle with no NAs and with levels: ",
             paste(.LEVELS, collapse=" "))
    return(paste(msg, collapse=""))
  }
  NULL
}
```

```r
#constraint(gr) <- "HasRangeTypeCol" # will fail

checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9
```

```r
levels <- c("gene", "transcript", "exon", "cds", "5utr", "3utr")
rangeType <- Rle(factor(c("cds", "gene"), levels=levels), c(8, 2))
```
mcols(gr)$rangeType <- rangeType
#constraint(gr) <- "HasRangeTypeCol" # OK
checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9

## Use is() to check whether the object has a given constraint or not:
#is(constraint(gr), "HasRangeTypeCol") # TRUE

mcols(gr)$rangeType[3] <- NA # will fail
mcols(gr)$rangeType[3] <- NA
checkConstraint(gr, new("HasRangeTypeCol")) # with GenomicRanges >= 1.7.9

## EXAMPLE 2: The GeneRanges constraint.
## ---------------------------------------------------------------------
## The GeneRanges constraint is defined on top of the HasRangeTypeCol
## constraint. It checks that all the ranges in the object are of type
## "gene".

setClass("GeneRanges", contains="HasRangeTypeCol")

## The checkConstraint() generic will check the HasRangeTypeCol constraint
## first, and, only if it's satisfied, it will then check the GeneRanges
## constraint.
setMethod("checkConstraint", c("GenomicRanges", "GeneRanges"),
  function(x, constraint, verbose=FALSE)
  {
    rangeType <- mcols(x)$rangeType
    if (!all(rangeType == "gene")) {
      msg <- c("all elements in 
        mcols(x)$rangeType 
      "
      "must be equal to "gene"")
      return(paste(msg, collapse=""))
    }
    NULL
  })

mcols(gr)$rangeType[] <- "gene"
# This replace the previous constraint (HasRangeTypeCol):
#constraint(gr) <- "GeneRanges" # OK
checkConstraint(gr, new("GeneRanges")) # with GenomicRanges >= 1.7.9

## is(constraint(gr), "GeneRanges") # TRUE
## However, 'gr' still indirectly has the HasRangeTypeCol constraint
## (because the GeneRanges constraint extends the HasRangeTypeCol
## constraint):
## is(constraint(gr), "HasRangeTypeCol") # TRUE

mcols(gr)$rangeType[] <- "exon" # will fail
mcols(gr)$rangeType[] <- "exon"
checkConstraint(gr, new("GeneRanges")) # with GenomicRanges >= 1.7.9
### EXAMPLE 3: The HasGCCol constraint.

The HasGCCol constraint checks that the constrained object has a unique "GC" metadata column, that this column is of type numeric, with no NAs, and that all the values in that column are $\geq 0$ and $\leq 1$.

```r
setClass("HasGCCol", contains="Constraint")
setMethod("checkConstraint", c("GenomicRanges", "HasGCCol"),
  function(x, constraint, verbose=FALSE)
  {
    x_mcols <- mcols(x)
    idx <- match("GC", colnames(x_mcols))
    if (length(idx) != 1L || is.na(idx)) {
      msg <- c("mcols(x) must have exactly ",
               "one column named \"GC\"")
      return(paste(msg, collapse=""))
    }
    GC <- x_mcols[[idx]]
    if (!is.numeric(GC) || S4Vectors:::anyMissing(GC) ||
        any(GC < 0) || any(GC > 1))
    {
      msg <- c("mcols(x)$GC must be a numeric vector ",
               "with no NAs and with values between 0 and 1")
      return(paste(msg, collapse=""))
    }
    NULL
  })
```

This replace the previous constraint (GeneRanges):
```
#constraint(gr) <- "HasGCCol" # OK
checkConstraint(gr, new("HasGCCol")) # with GenomicRanges >= 1.7.9

#is(constraint(gr), "HasGCCol") # TRUE
#is(constraint(gr), "GeneRanges") # FALSE
#is(constraint(gr), "HasRangeTypeCol") # FALSE
```

### EXAMPLE 4: The HighGCRanges constraint.

The HighGCRanges constraint is defined on top of the HasGCCol constraint. It checks that all the ranges in the object have a GC content $\geq 0.5$.

```r
setClass("HighGCRanges", contains="HasGCCol")
```

```
# The checkConstraint() generic will check the HasGCCol constraint
# first, and, if it's statisfied, it will then check the HighGCRanges
# constraint.
setMethod("checkConstraint", c("GenomicRanges", "HighGCRanges"),
  function(x, constraint, verbose=FALSE)
  {
    GC <- mcols(x)$GC
  })
```
if (!all(GC >= 0.5)) {
    msg <- c("all elements in 'mcols(x)$GC",
              "must be >= 0.5")
    return(paste(msg, collapse=""))
} else {
    NULL
}

#\dontrun{
#constraint(gr) <- "HighGCRanges"  # will fail
#}
checkConstraint(gr, new("HighGCRanges"))  # with GenomicRanges >= 1.7.9
mcols(gr)$GC[6:10] <- 0.5
#constraint(gr) <- "HighGCRanges"  # OK
checkConstraint(gr, new("HighGCRanges"))  # with GenomicRanges >= 1.7.9

#is(constraint(gr), "HighGCRanges")  # TRUE
#is(constraint(gr), "HasGCCol")  # TRUE

### EXAMPLE 5: The HighGCGeneRanges constraint.
###-------------------------------------------------------------------------------
### The HighGCGeneRanges constraint is the combination (AND) of the
### GeneRanges and HighGCRanges constraints.

setClass("HighGCGeneRanges", contains=c("GeneRanges", "HighGCRanges"))

# No need to define a method for this constraint: the checkConstraint()
# generic will automatically check the GeneRanges and HighGCRanges
# constraints.

#constraint(gr) <- "HighGCGeneRanges"  # OK
checkConstraint(gr, new("HighGCGeneRanges"))  # with GenomicRanges >= 1.7.9

#is(constraint(gr), "HighGCGeneRanges")  # TRUE
#is(constraint(gr), "HighGCRanges")  # TRUE
#is(constraint(gr), "HasGCCol")  # TRUE
#is(constraint(gr), "GeneRanges")  # TRUE
#is(constraint(gr), "HasRangeTypeCol")  # TRUE

### See how all the individual constraints are checked (from less
### specific to more specific constraints):
#checkConstraint(gr, constraint(gr), verbose=TRUE)
checkConstraint(gr, new("HighGCGeneRanges"), verbose=TRUE)  # with
            # GenomicRanges
            # >= 1.7.9

### See all the "checkConstraint" methods:
showMethods("checkConstraint")
Description

coverage methods for GRanges and GRangesList objects.

NOTE: The coverage generic function and methods for Ranges and RangesList objects are defined and documented in the IRanges package. Methods for GAlignments and GAlignmentPairs objects are defined and documented in the GenomicAlignments package.

Usage

## S4 method for signature 'GenomicRanges'
coverage(x, shift=0L, width=NULL, weight=1L,
method=c("auto", "sort", "hash"))

## S4 method for signature 'GRangesList'
coverage(x, shift=0L, width=NULL, weight=1L,
method=c("auto", "sort", "hash"))

Arguments

x
A GRanges or GRangesList object.

shift
A numeric vector or a list-like object. If numeric, it must be parallel to x (recycled if necessary). If a list-like object, it must have 1 list element per seqlevel in x, and its names must be exactly seqlevels(x).
Alternatively, shift can also be specified as a single string naming a metadata column in x (i.e. a column in mcols(x)) to be used as the shift vector.
See ?coverage in the IRanges package for more information about this argument.

width
Either NULL (the default), or an integer vector. If NULL, it is replaced with seqlengths(x). Otherwise, the vector must have the length and names of seqlengths(x) and contain NAs or non-negative integers.
See ?coverage in the IRanges package for more information about this argument.

weight
A numeric vector or a list-like object. If numeric, it must be parallel to x (recycled if necessary). If a list-like object, it must have 1 list element per seqlevel in x, and its names must be exactly seqlevels(x).
Alternatively, weight can also be specified as a single string naming a metadata column in x (i.e. a column in mcols(x)) to be used as the weight vector.
See ?coverage in the IRanges package for more information about this argument.

method
See ?coverage in the IRanges package for a description of this argument.

Details

When x is a GRangesList object, coverage(x, ...) is equivalent to coverage(unlist(x), ...).

Value

A named RleList object with one coverage vector per seqlevel in x.

- `coverage-methods` in the `GenomicAlignments` package.
- `RleList` objects in the `IRanges` package.
- `GRanges` and `GRangesList` objects.

Examples

```r
## Coverage of a GRanges object:
gr <- GRanges(
  seqnames=Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
  ranges=IRanges(1:10, end=10),
  strand=Rle(strand(c("-", "+", "-", "+", "-")), c(1, 2, 2, 3, 2)),
  seqlengths=c(chr1=11, chr2=12, chr3=13))
cvg <- coverage(gr)
pcvg <- coverage(gr[strand(gr) == "+"])
mcvg <- coverage(gr[strand(gr) == "-" ])
scvg <- coverage(gr[strand(gr) == "*" ])
stopifnot(identical(pcvg + mcvg + scvg, cvg))

## Coverage of a GRangesList object:
gr1 <- GRanges(seqnames="chr2",
  ranges=IRanges(3, 6),
  strand = "+")
gr2 <- GRanges(seqnames=c("chr1", "chr1"),
  ranges=IRanges(c(7,13), width=3),
  strand=c("+", "-"))
gr3 <- GRanges(seqnames=c("chr1", "chr2"),
  ranges=IRanges(c(1, 4), c(3, 9)),
  strand=c("-", "-"))
gr1 <- GRangesList(gr1=gr1, gr2=gr2, gr3=gr3)
stopifnot(identical(coverage(gr1), coverage(unlist(gr1))))
```

DelegatingGenomicRanges-class

**DelegatingGenomicRanges objects**

Description

The `DelegatingGenomicRanges` class implements the virtual `GenomicRanges` class using a delegate `GenomicRanges`. This enables developers to create `GenomicRanges` subclasses that add specialized columns or other structure, while remaining agnostic to how the data are actually stored. See the Extending GenomicRanges vignette.

Author(s)

M. Lawrence
**findOverlaps-methods**

**Finding overlapping genomic ranges**

**Description**

Various methods for finding/counting overlaps between objects containing genomic ranges. This
man page describes the methods that operate on GenomicRanges and GRangesList objects.

NOTE: The findOverlaps generic function and methods for Ranges and RangesList objects are
defined and documented in the IRanges package. The methods for GAlignments, GAlignmentPairs,
and GAlignmentsList objects are defined and documented in the GenomicAlignments package.

GenomicRanges and GRangesList objects also support countOverlaps, overlapsAny, and subsetByOverlaps
thanks to the default methods defined in the IRanges package and to the findOverlaps and
countOverlaps methods defined in this package and documented below.

**Usage**

```r
## S4 method for signature 'GenomicRanges,GenomicRanges'
findOverlaps(query, subject,
             maxgap=0L, minoverlap=1L,
             type=c("any", "start", "end", "within", "equal"),
             select=c("all", "first", "last", "arbitrary"),
             ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
countOverlaps(query, subject,
               maxgap=0L, minoverlap=1L,
               type=c("any", "start", "end", "within", "equal"),
               ignore.strand=FALSE)
```

**Arguments**

- `query, subject` A GRanges or GRangesList object.
- `maxgap, minoverlap, type`
  See findOverlaps in the IRanges package for a description of these arguments.
- `select` When select is "all" (the default), the results are returned as a Hits object.
  Otherwise the returned value is an integer vector parallel to query (i.e. same length) containing the first, last, or arbitrary overlapping interval in subject,
  with NA indicating intervals that did not overlap any intervals in subject.
- `ignore.strand` When set to TRUE, the strand information is ignored in the overlap calculations.

**Details**

When the query and the subject are GRanges or GRangesList objects, findOverlaps uses the
triplet (sequence name, range, strand) to determine which features (see paragraph below for the
definition of feature) from the query overlap which features in the subject, where a strand value
of "*" is treated as occurring on both the "+" and "-" strand. An overlap is recorded when a
feature in the query and a feature in the subject have the same sequence name, have a compatible
pairing of strands (e.g. "+"/+", "-"/-", "*"/+"*, "*"/-"*, etc.), and satisfy the interval overlap
requirements.
In the context of `findOverlaps`, a feature is a collection of ranges that are treated as a single entity. For `GRanges` objects, a feature is a single range; while for `GRangesList` objects, a feature is a list element containing a set of ranges. In the results, the features are referred to by number, which run from 1 to `length(query)/length(subject)`.

**Value**

For `findOverlaps` either a `Hits` object when `select="all"` or an integer vector otherwise. For `countOverlaps` an integer vector containing the tabulated query overlap hits.

**Author(s)**

P. Aboyoun, S. Falcon, M. Lawrence, and H. Pagès

**See Also**

- The `Hits` class for representing a set of hits between 2 vector-like objects.
- The `findOverlaps` generic function defined in the `IRanges` package.
- The `GNCList` constructor and class for preprocessing and representing a `GenomicRanges` or `GRangesList` object as a data structure based on Nested Containment Lists.
- The `GRanges` and `GRangesList` classes.

**Examples**

```r
## BASIC EXAMPLES

## GRanges object:
gr <- GRanges(
    seqnames=Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
    ranges=IRanges(1:10, width=10:1, names=head(letters,10)),
    strand=Rle(strand(c("-", "+", "*", "*", "-")), c(1, 2, 3, 2)),
    score=1:10,
    GC=seq(1, 0, length=10)
)
gr

## GRangesList object:
gr1 <- GRanges(seqnames="chr2", ranges=IRanges(4:3, 6),
    strand="*", score=5:4, GC=0.45)
gr2 <- GRanges(seqnames=c("chr1", "chr1"),
    ranges=IRanges(c(7,13), width=3),
    strand=c("*", "-"), score=3:4, GC=c(0.3, 0.5))
gr3 <- GRanges(seqnames=c("chr1", "chr2"),
    ranges=IRanges(c(4, 3, 9)),
    strand=c("-", "-"), score= seq(6L, 2L), GC=c(0.4, 0.1))
gr1 <- GRangesList("gr1"=gr1, "gr2"=gr2, "gr3"=gr3)

## Overlapping two GRanges objects:
table(!is.na(findOverlaps(gr, gr1, select="arbitrary")))
countOverlaps(gr, gr1)
findOverlaps(gr, gr1)
subsetByOverlaps(gr, gr1)
```
countOverlaps(gr, gr1, type="start")
findOverlaps(gr, gr1, type="start")
subsetByOverlaps(gr, gr1, type="start")

findOverlaps(gr, gr1, select="first")

GenomicRanges-comparison

Comparing and ordering genomic ranges

Description

Methods for comparing and ordering the elements in one or more GenomicRanges objects.
Usage

```r
## duplicated()
## ------------
## S4 method for signature 'GenomicRanges'
duplicated(x, incomparables=FALSE, fromLast=FALSE,
    method=c("auto", "quick", "hash"))

## match() & selfmatch()
## ---------------------
## S4 method for signature 'GenomicRanges,GenomicRanges'
match(x, table, nomatch=NA_integer_, incomparables=NULL,
    method=c("auto", "quick", "hash"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
selmatch(x, method=c("auto", "quick", "hash"), ignore.strand=FALSE)

## order() and related methods
## ----------------------------
## S4 method for signature 'GenomicRanges'
is.unsorted(x, na.rm=FALSE, strictly=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
order(..., na.last=TRUE, decreasing=FALSE, method=c("shell", "radix"))

## S4 method for signature 'GenomicRanges'
sort(x, decreasing=FALSE, ignore.strand=FALSE, by)

## S4 method for signature 'GenomicRanges'
rank(x, na.last=TRUE,
    ties.method=c("average", "first", "random", "max", "min"))

## Generalized parallel comparison of 2 GenomicRanges objects
## ----------------------------------------------------------
## S4 method for signature 'GenomicRanges,GenomicRanges'
pcompare(x, y)
```

Arguments

- `x, table, y` GenomicRanges objects.
- `incomparables` Not supported.
- `fromLast, method, nomatch` See `?Ranges-comparison` in the IRanges package for a description of these arguments.
- `ignore.strand` Whether or not the strand should be ignored when comparing 2 genomic ranges.
- `na.rm` Ignored.
- `strictly` Logical indicating if the check should be for strictly increasing values.
One or more `GenomicRanges` objects. The `GenomicRanges` objects after the first one are used to break ties.

- **na.last** Ignored.
- **decreasing** `TRUE` or `FALSE`.
- **ties.method** A character string specifying how ties are treated. Only "first" is supported for now.
- **by** An optional formula that is resolved against `as.env(x)`; the resulting variables are passed to `order` to generate the ordering permutation.

### Details

Two elements of a `GenomicRanges` object (i.e. two genomic ranges) are considered equal iff they are on the same underlying sequence and strand, and have the same start and width. `duplicated()` and `unique()` on a `GenomicRanges` object are conforming to this.

The "natural order" for the elements of a `GenomicRanges` object is to order them (a) first by sequence level, (b) then by strand, (c) then by start, (d) and finally by width. This way, the space of genomic ranges is totally ordered. Note that the reduce method for `GenomicRanges` uses this "natural order" implicitly. Also, note that, because we already do (c) and (d) for regular ranges (see `?Ranges-comparison`), genomic ranges that belong to the same underlying sequence and strand are ordered like regular ranges.

- `is.unsorted()`, `order()`, `sort()`, and `rank()` on a `GenomicRanges` object behave accordingly to this "natural order".
- `==`, `!=`, `<=`, `>=`, `<` and `>` on `GenomicRanges` objects also behave accordingly to this "natural order".

### Author(s)

H. Pagès, `is.unsorted` contributed by Pete Hickey

is.unsorted(gr2)  # TRUE
is.unsorted(gr2, ignore.strand=TRUE)  # FALSE
```

### TODO: Broken. Please fix!
```r
#sort(gr, by = ~ seqnames + start + end)  # equivalent to (but slower than) above

score(gr) <- rev(seq_len(length(gr)))
```

### TODO: Broken. Please fix!
```r
#sort(gr, by = ~ score)
rank(gr)
```

### F. GENERALIZED ELEMENT-WISE COMPARISON OF 2 GenomicRanges OBJECTS
# GenomicRangesList-class

## Description

A GenomicRangesList is a list of GenomicRanges. It is a virtual class: SimpleGenomicRangesList is the basic implementation. The subclass GRangesList provides special behavior and is particularly efficient for storing a large number of elements.

## Constructor

GenomicRangesList(...) : Constructs a SimpleGenomicRangesList with elements taken from the arguments in .... If the only argument is a list, the elements are taken from that list.

## Coercion

as(from, "GenomicRangesList") : Supported from types include:

**RangedDataList** Each element of from is coerced to a GenomicRanges.

as(from, "RangedDataList") : Supported from types include:

**GenomicRangesList** Each element of from is coerced to a RangedData.

## Author(s)

Michael Lawrence

## See Also

GRangesList, which differs from SimpleGenomicRangesList in that the GRangesList treats its elements as single, compound ranges, particularly in overlap operations. SimpleGenomicRangesList is just a barebones list for now, without that compound semantic.
Manipulating genomic variables

Description

A genomic variable is a variable defined along a genome. Here are 2 ways a genomic variable is generally represented in Bioconductor:

1. as a named RleList object with one list element per chromosome;
2. as a metadata column on a disjoint GRanges object.

This man page documents tools for switching from one form to the other.

Usage

bindAsGRanges(...)
mcolAsRleList(x, varname)
binnedAverage(bins, numvar, varname)

Arguments

... One or more genomic variables in the form of named RleList objects.

x A disjoint GRanges object with metadata columns on it. A GRanges object is said to be disjoint if it contains ranges that do not overlap with each other. This can be tested with isDisjoint. See `?isDisjoint.GenomicRanges-method` for more information about the isDisjoint method for GRanges objects.

varname The name of the genomic variable.

For mcolAsRleList this must be the name of the metadata column on x to be turned into an RleList object.

For binnedAverage this will be the name of the metadata column that contains the binned average in the returned object.

bins A GRanges object representing the genomic bins. Typically obtained by calling tileGenome with cut.last.tile.in.chrom=TRUE.

numvar A named RleList object representing a numerical variable defined along the genome covered by bins (which is the genome described by seqinfo(bins)).

Details

bindAsGRanges allows to switch the representation of one or more genomic variables from the named RleList form to the metadata column on a disjoint GRanges object form by binding the supplied named RleList objects together and putting them on the same GRanges object. This transformation is lossless.

mcolAsRleList performs the opposite transformation and is also lossless (however the circularity flags and genome information in seqinfo(x) won’t propagate). It works for any metadata column on x that can be put in Rle form i.e. that is an atomic vector or a factor.

binnedAverage computes the binned average of a numerical variable defined along a genome.
Value

For bindAsGRanges: a GRanges object with 1 metadata column per supplied genomic variable.
For mcolAsRleList: a named RleList object with 1 list element per seqlevel in x.
For binnedAverage: the GRanges object bins with an additional metadata column named varname containing the binned average.

Author(s)

H. Pagès

- The tileGenome function for putting tiles on a genome.
- GRanges objects and isDisjoint.GenomicRanges-method for the isDisjoint method for GenomicRanges objects.

Examples

```r
## A. TWO WAYS TO REPRESENT A GENOMIC VARIABLE
##----------------------------------------------
## 1) As a named RleList object
##----------------------------------------------
## Let's create a genomic variable in the "named RleList" form:
library(BSgenome.Scerevisiae.UCSC.sacCer2)
set.seed(55)
my_var <- RleList(
  lapply(seqlengths(Scerevisiae),
    function(seqlen) {
      tmp <- sample(50L, seqlen, replace=TRUE)
      Rle(cumsum(tmp - rev(tmp)))
    })),
  compress=FALSE)
my_var

## 2) As a metadata column on a disjoint GRanges object
##----------------------------------------------
gr1 <- bindAsGRanges(my_var=my_var)
gr1
gr2 <- GRanges(c("chrI:1-150",
  "chrI:211-285",
  "chrI:291-377",
  "chrV:51-60"),
  score=c(0.4, 8, -10, 2.2),
  id=letters[1:4],
  seqinfo=seqinfo(Scerevisiae))
gr2

## Going back to the "named RleList" form:
```
mcolAsRleList(gr1, "my_var")
score <- mcolAsRleList(gr2, "score")
score
id <- mcolAsRleList(gr2, "id")
id
bindAsGRanges(score=score, id=id)

## Bind 'my_var', 'score', and 'id' together:
gr3 <- bindAsGRanges(my_var=my_var, score=score, id=id)

## Sanity checks:
stopifnot(identical(my_var, mcolAsRleList(gr3, "my_var")))
stopifnot(identical(score, mcolAsRleList(gr3, "score")))
stopifnot(identical(id, mcolAsRleList(gr3, "id")))
gr2b <- bindAsGRanges(score=score, id=id)
seqinfo(gr2b) <- seqinfo(gr2)
stopifnot(identical(gr2, gr2b))

## B. BIND TOGETHER THE COVERAGE OF SEVERAL BAM FILES

library(pasillaBamSubset)
library(GenomicAlignments)
untreated1_cvg <- coverage(BamFile(untreated1_chr4()))
untreated3_cvg <- coverage(BamFile(untreated3_chr4()))
all_cvg <- bindAsGRanges(untreated1=untreated1_cvg, untreated3=untreated3_cvg)

## Keep regions with coverage:
all_cvg[with(mcols(all_cvg), untreated1 + untreated3 >= 1)]

## Plot the coverage profiles with the Gviz package:
library(Gviz)
plotNumvars <- function(numvars, region, name="numvars", ...) {
  stopifnot(is(numvars, "GRanges"))
  stopifnot(is(region, "GRanges"), length(region) == 1L)
  gtrack <- GenomeAxisTrack()
  dtrack <- DataTrack(numvars,
    chromosome=as.character(seqnames(region)),
    name=name,
    groups=colnames(mcols(numvars)), type="l", ...)
  plotTracks(list(gtrack, dtrack), from=start(region), to=end(region))
}
plotNumvars(all_cvg, GRanges("chr4:1-25000"),
  "coverage", col=c("red", "blue"))
plotNumvars(all_cvg, GRanges("chr4:1.03e6-1.08e6"),
  "coverage", col=c("red", "blue"))

## Sanity checks:
stopifnot(identical(untreated1_cvg, mcolAsRleList(all_cvg, "untreated1")))
stopifnot(identical(untreated3_cvg, mcolAsRleList(all_cvg, "untreated3")))

### C. COMPUTE THE BINNED AVERAGE OF A NUMERICAL VARIABLE DEFINED ALONG A GENOME
In some applications (e.g., visualization), there is the need to compute the average of a genomic variable for a set of predefined fixed-width regions (sometimes called "bins"). Let's use `tileGenome()` to create such a set of bins:

```r
bins1 <- tileGenome(seqinfo(Scerevisiae), tilewidth=100, cut.last.tile.in.chrom=TRUE)
```

Compute the binned average for `my_var` and `score`:

```r
bins1 <- binnedAverage(bins1, my_var, "binned_var")
bins1 <- binnedAverage(bins1, score, "binned_score")
bins1
```

Binned average in "named RleList" form:

```r
binned_var1 <- mcolAsRleList(bins1, "binned_var")
binned_var1
stopifnot(all.equal(mean(my_var), mean(binned_var1))) # sanity check
```

```r
mcolAsRleList(bins1, "binned_score")
```

With bigger bins:

```r
bins2 <- tileGenome(seqinfo(Scerevisiae), tilewidth=50000, cut.last.tile.in.chrom=TRUE)
bins2 <- binnedAverage(bins2, my_var, "binned_var")
bins2 <- binnedAverage(bins2, score, "binned_score")
bins2
binned_var2 <- mcolAsRleList(bins2, "binned_var")
binned_var2
stopifnot(all.equal(mean(my_var), mean(binned_var2))) # sanity check
```

```r
mcolAsRleList(bins2, "binned_score")
```

Not surprisingly, the "binned" variables are much more compact in memory than the original variables (they contain much less runs):

```r
object.size(my_var)
object.size(binned_var1)
object.size(binned_var2)
```

---

**GNCLList-class**

**Description**

The GNCLList class is a container for storing the Nested Containment List representation of a vector of genomic ranges (typically represented as a GRanges object). To preprocess a GRanges object, simply call the GNCList constructor function on it. The resulting GNCList object can then be used for efficient overlap-based operations on the genomic ranges.

**Usage**

```r
GNCLList(x)
```
Arguments

x  
The GRanges (or more generally GenomicRanges) object to preprocess.

Details

The IRanges package also defines the NCList and NCLists constructors and classes for preprocessing and representing a Ranges or RangesList object as a data structure based on Nested Containment Lists.

Note that GNCList objects (introduced in BioC 3.1) are replacements for GIIntervalTree objects (BioC < 3.1).

See ?NCList in the IRanges package for some important differences between the new algorithm based on Nested Containment Lists and the old algorithm based on interval trees. In particular, the new algorithm supports preprocessing of a GenomicRanges object with ranges defined on circular sequences (e.g. on the mitochondrial chromosome). See below for some examples.

Value

A GNCList object.

Author(s)

H. Pagès

References

See Also

• The NCList and NCLists constructors and classes defined in the IRanges package.
• findOverlaps for finding/counting interval overlaps between two range-based objects.
• GRanges objects.

Examples

```r
## The examples below are for illustration purpose only and do NOT
## reflect typical usage. This is because, for a one time use, it is
## NOT advised to explicitly preprocess the input for findOverlaps()
## or countOverlaps(). These functions will take care of it and do a
## better job at it (by preprocessing only what's needed when it's
## needed, and release memory as they go).
## ---------------------------------------------------------------------
## PREPROCESS QUERY OR SUBJECT
## ---------------------------------------------------------------------

query <- GRanges(Rle(c("chrM", "chr1", "chrM", "chr1"), 4:1),
                 IRanges(1:10, width=5), strand=rep(c("+", "-"), 5))
subject <- GRanges(Rle(c("chr1", "chr2", "chrM"), 3:1),
                    IRanges(6:1, width=5), strand="+")
```
Either the query or the subject of findOverlaps() can be preprocessed:

```r
ppsubject <- GNCList(subject)
hits1a <- findOverlaps(query, ppsubject)
hits1a
hits1b <- findOverlaps(query, ppsubject, ignore.strand=TRUE)
hits1b

ppquery <- GNCList(query)
hits2a <- findOverlaps(ppquery, subject)
hits2a
hits2b <- findOverlaps(ppquery, subject, ignore.strand=TRUE)
hits2b
```

Note that 'hits1a' and 'hits2a' contain the same hits but not necessarily in the same order.

```r
stopifnot(identical(sort(hits1a), sort(hits2a)))
```

Same for 'hits1b' and 'hits2b'.

```r
stopifnot(identical(sort(hits1b), sort(hits2b)))
```

WITH CIRCULAR SEQUENCES

```r
seqinfo <- Seqinfo(c("chr1", "chr2", "chrM"),
  seqlengths=c(100, 50, 10),
  isCircular=c(FALSE, FALSE, TRUE))
seqinfo(query) <- seqinfo[seqlevels(query)]
seqinfo(subject) <- seqinfo[seqlevels(subject)]

ppsubject <- GNCList(subject)
hits3 <- findOverlaps(query, ppsubject)
hits3
```

Circularity introduces more hits:

```r
stopifnot(all(hits1a %in% hits3))
new_hits <- setdiff(hits3, hits1a)
query[queryHits(new_hits)]
subject[subjectHits(new_hits)]
# positions 11:13 on chrM are the same as positions 1:3
```

Sanity checks:

```r
stopifnot(identical(new_hits, Hits(9, 6, 10, 6, sort.by.query=TRUE)))
ppquery <- GNCList(query)
hits4 <- findOverlaps(ppquery, subject)
stopifnot(identical(sort(hits3), sort(hits4)))
```

GPos-class

GPos objects

Description

The GPos class is a container for storing a set of genomic positions, that is, genomic ranges of width 1. Even though a GRanges object can be used for that, using a GPos object can be much
more memory-efficient, especially when the object contains long runs of adjacent positions.

Usage

GPos(pos_runs)  # constructor function

Arguments

pos_runs  A GRanges object (or any other GenomicRanges derivative) where each range is interpreted as a run of adjacent genomic positions. If pos_runs is not a GenomicRanges object, GPos() first tries to coerce it to one with as(pos_runs, "GenomicRanges", strict = FALSE).

Value

A GPos object.

Accessors

Getters:  GPos objects support the same set of getters as GRanges objects (i.e. seqnames(), start(), end(), ranges(), strand(), mcols(), seqinfo(), etc...), plus the pos() getter which is equivalent to start() or end(). See ?GRanges for the list of getters supported by GRanges objects.

Note that a GPos object cannot hold names i.e. names() always returns NULL on it.

Setters:  Like GRanges objects, GPos objects support the following setters:
   • The mcols() and metadata() setters.
   • The family of setters that operate on the seqinfo component of an object: seqlevels(), seqlevelsStyle(), seqlengths(), isCircular(), genome(), and seqinfo(). These setters are defined and documented in the GenomeInfoDb package.

However, there is no seqnames(), pos(), or strand() setter for GPos objects at the moment (although they might be added in the future).

Coercion

From GenomicRanges to GPos: A GenomicRanges object x in which all the ranges have a width of 1 can be coerced to a GPos object with as(x, "GPos"). The names on x are not propagated (a warning is issued if x has names on it).

From GPos to GRanges: A GPos object x can be coerced to a GRanges object with as(x, "GRanges"). However be aware that the resulting object can use thousands times (or more) memory than x! See "MEMORY USAGE" in the Examples section below.

From GPos to ordinary R objects: Like with a GRanges object, as.character(), as.factor(), and as.data.frame() work with a GPos object x. Note that as.data.frame(x) returns a data frame with a pos column (containing pos(x)) instead of the start, end, and width columns that one gets when x is a GRanges object.

Subsetting

A GPos object can be subsetted exactly like a GRanges object.

Combining

GPos objects can be combined (a.k.a. appended) with c() or append().
Splitting and Relisting

Like with a GRanges object, split() and relist() work with a GPos object x. Note that they return a GenomicRangesList object instead of a GRangesList object.

Note

Like for any Vector derivative, the length of a GPos object cannot exceed .Machine$integer.max (i.e. $2^{31}$ on most platforms). GPos() will return an error if pos_runs contains too many genomic positions.

Author(s)

Hervé Pagès; based on ideas borrowed from Georg Stricker <georg.stricker@in.tum.de> and Julien Gagneur <gagneur@in.tum.de>

Examples

```r
## ---------------------------------------------------------------------
## BASIC EXAMPLES
## ---------------------------------------------------------------------

## Example 1:
gpos1 <- GPos(c("chr1:44-53", "chr1:5-10", "chr2:2-5"))
gpos1

length(gpos1)
seqnames(gpos1)
pos(gpos1)  # same as 'start(gpos1)' and 'end(gpos1)'
strand(gpos1)
as.character(gpos1)
as.data.frame(gpos1)
as(gpos1, "GRanges")
as.data.frame(as(gpos1, "GRanges"))
gpos1[9:17]

## Example 2:
pos_runs <- GRanges("chr1", IRanges(c(1, 6, 12, 17), c(5, 10, 16, 20)),
                        strand=c("+", "-", "-", "+"))
gpos2 <- GPos(pos_runs)
gpos2
```
## Example 3:
gpos3A <- gpos3B <- GPos(c("chrI:1-1000", "chrI:1005-2000"))
npos <- length(gpos3A)
mcols(gpos3A)$sample <- Rle("sA")
sA_counts <- sample(10, npos, replace=TRUE)
mcols(gpos3A)$counts <- sA_counts
mcols(gpos3B)$sample <- Rle("sB")
sB_counts <- sample(10, npos, replace=TRUE)
mcols(gpos3B)$counts <- sB_counts
gpos3 <- c(gpos3A, gpos3B)
gpos3

## Example 4:
library(BSgenome.Scerevisiae.UCSC.sacCer2)
genome <- BSgenome.Scerevisiae.UCSC.sacCer2
gpos4 <- GPos(seqinfo(genome))
gpos4 # all the positions along the genome are represented
mcols(gpos4)$dna <- do.call("c", unname(as.list(genome)))
gpos4

## Note however that, like for any Vector derivative, the length of a
## GPos object cannot exceed `.Machine$integer.max` (i.e. 2^31 on most
## platforms) so the above only works with a "small" genome.
## For example it doesn’t work with the Human genome:
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
## Not run:
GPos(seqinfo(TxDB.Hsapiens.UCSC.hg19.knownGene)) # error!
## End(Not run)

## You can use isSmallGenome() to check upfront whether the genome is
## "small" or not.
isSmallGenome(genome)
isSmallGenome(TxDB.Hsapiens.UCSC.hg19.knownGene)

## MEMOETY USAGE
#  ___________________________________________________________________
#  Coercion to GRanges works...
gr4 <- as(gpos4, "GRanges")
gr4
## ... but is generally not a good idea:
object.size(gpos4)
object.size(gr4) # 6951 times bigger than the GPos object!

## Shuffling the order of the positions impacts memory usage:
gpos4r <- rev(gpos4)
object.size(gpos4r) # significantly
gpos4s <- sample(gpos4)
object.size(gpos4s) # even worse!
## AN IMPORTANT NOTE: In the worst situations, GPos still performs as good as a GRanges object.

object.size(as(gpos4r, "GRanges")) # same size as 'gpos4r'
object.size(as(gpos4s, "GRanges")) # same size as 'gpos4s'

## Best case scenario is when the object is strictly sorted (i.e. positions are in strict ascending order).

%%
%% This can be checked with:
%%
is.unsorted(gpos4, strict=TRUE) # 'gpos4' is strictly sorted

## USING MEMORY-EFFICIENT METADATA COLUMNS

%%

## In order to keep memory usage as low as possible, it is recommended to use a memory-efficient representation of the metadata columns that we want to set on the object. Rle's are particularly well suited for this, especially if the metadata columns contain long runs of identical values. This is the case for example if we want to use a GPos object to represent the coverage of sequencing reads along a genome.

## Example 5:

```r
library(pasillaBamSubset)
library(Rsamtools) # for the BamFile() constructor function
bamfile1 <- BamFile(untreated1_chr4())
bamfile2 <- BamFile(untreated3_chr4())
gpos5 <- GPos(seqinfo(bamfile1))
library(GenomicAlignments) # for "coverage" method for BamFile objects
cov1 <- unlist(coverage(bamfile1), use.names=FALSE)
cov2 <- unlist(coverage(bamfile2), use.names=FALSE)
mcols(gpos5) <- DataFrame(cov1, cov2)
gpos5
object.size(gpos5) # lightweight
```

## Keep only the positions where coverage is at least 10 in one of the 2 samples:

```r
gpos5[mcols(gpos5)$cov1 >= 10 | mcols(gpos5)$cov2 >= 10]
```

## USING A GPos OBJECT IN A SummarizedExperiment OBJECT

%%

## Because the GPos class extends the GenomicRanges virtual class, a GPos object can be used as the rowRanges component of a SummarizedExperiment object.

## As a 1st example, we show how the counts for samples sA and sB in 'gpos3' can be stored in a SummarizedExperiment object where the rows correspond to unique genomic positions and the columns to samples:

```r
library(SummarizedExperiment)
counts <- cbind(sA=sA_counts, sB=sB_counts)
mcols(gpos3A) <- NULL
rse3 <- SummarizedExperiment(list(counts=counts), rowRanges=gpos3A)
rse3
rowRanges(rse3)
head(assay(rse3))
```
Finally we show how the coverage data from Example 5 can be easily stored in a lightweight SummarizedExperiment object:

cov <- mcols(gpos5)
mcols(gpos5) <- NULL
rse5 <- SummarizedExperiment(list(cov=cov), rowRanges=gpos5)
rse5
rowRanges(rse5)
assay(rse5)

## Keep only the positions where coverage is at least 10 in one of the 2 samples:
rse5[assay(rse5)$cov1 >= 10 | assay(rse5)$cov2 >= 10]

---

### Description

The GRanges class is a container for the genomic locations and their associated annotations.

### Details

GRanges is a vector of genomic locations and associated annotations. Each element in the vector is comprised of a sequence name, an interval, a strand, and optional metadata columns (e.g. score, GC content, etc.). This information is stored in four components:

- **seqnames**: a `factor` Rle object containing the sequence names.
- **ranges**: an IRanges object containing the ranges.
- **strand**: a `factor` Rle object containing the strand information.
- **mcols**: a DataFrame object containing the metadata columns. Columns cannot be named "seqnames", "ranges", "strand", "seqlevels", "seqlengths", "isCircular", "start", "end", "width", or "element".
- **seqinfo**: a Seqinfo object containing information about the set of genomic sequences present in the GRanges object.

### Constructor

GRanges(seqnames=NULL, ranges=NULL, strand=NULL, ..., seqlengths=NULL, seqinfo=NULL)

Creates a GRanges object.

- **seqnames**: NULL, or an Rle object, character vector, or factor containing the sequence names.
- **ranges**: NULL, or an IRanges object containing the ranges.
- **strand**: NULL, or an Rle object, character vector, or factor containing the strand information.
- **seqlengths**: NULL, or an integer vector named with levels(seqnames) and containing the lengths (or NA) for each level in levels(seqnames).
- **seqinfo**: NULL, or a Seqinfo object containing allowed sequence names, lengths (or NA), and circularity flag, for each level in levels(seqnames).

If ranges is not supplied and/or NULL then the constructor proceeds in 2 steps:
1. An initial GRanges object is created with `as(seqnames, "GRanges")`.
2. Then this GRanges object is updated according to whatever non-NULL remaining arguments were passed to the call to `GRanges()`.

As a consequence of this behavior, `GRanges(x)` is equivalent to `as(x, "GRanges")`.

### Coercion

In the code snippets below, `x` is a GRanges object.

#### `as(from, "GRanges")`:
Creates a GRanges object from a character vector, a factor, or a RangedData, or RangesList object.

When `from` is a character vector (or a factor), each element in it must represent a genomic range in format `chr1:2501-2800` (unstranded range) or `chr1:2501-2800:+` (stranded range). `..` is also supported as a separator between the start and end positions. Strand can be `+`, `-`, `*`, or missing. The names on `from` are propagated to the returned GRanges object. See `as.character()` and `as.factor()` below for the reverse transformations.

Coercing a data.frame or DataFrame into a GRanges object is also supported. See `makeGRangesFromDataFrame` for the details.

#### `as(from, "RangedData")`:
Creates a RangedData object from a GRanges object. The `strand` and metadata columns become columns in the result. The `seqlengths(from)`, `isCircular(from)`, and `genome(from)` vectors are stored in the metadata columns of `ranges(rd)`.

#### `as(from, "RangesList")`:
Creates a RangesList object from a GRanges object. The `strand` and metadata columns become inner metadata columns (i.e. metadata columns on the ranges). The `seqlengths(from)`, `isCircular(from)`, and `genome(from)` vectors become the metadata columns.

#### `as.character(x, ignore.strand=FALSE)`:
Turn GRanges object `x` into a character vector where each range in `x` is represented by a string in format `chr1:2501-2800:+`. If `ignore.strand` is `TRUE` or if all the ranges in `x` are unstranded (i.e. their strand is set to `*`), then all the strings in the output are in format `chr1:2501-2800`.

The names on `x` are propagated to the returned character vector. Its metadata (`metadata(x)`) and metadata columns (`mcols(x)`) are ignored.

See `as(from, "GRanges")` above for the reverse transformation.

#### `as.factor(x)`:
Equivalent to

```r
factor(as.character(x), levels=as.character(sort(unique(x))))
```

See `as(from, "GRanges")` above for the reverse transformation.

Note that `table(x)` is supported on a GRanges object. It is equivalent to, but much faster than, `table(as.factor(x))`.

#### `as.data.frame(x, row.names = NULL, optional = FALSE, ...)`:
Creates a data.frame with columns `seqnames` (factor), `start` (integer), `end` (integer), `width` (integer), `strand` (factor), as well as the additional metadata columns stored in `mcols(x)`. Pass an explicit `stringsAsFactors=TRUE/FALSE` argument via `...` to override the default conversions for the metadata columns in `mcols(x)`.

#### `as(from, "Grouping")`:
Creates a ManyToOneGrouping object that groups `from` by `seqname`, `strand`, `start` and `end` (same as the default sort order). This makes it convenient, for example, to aggregate a GenomicRanges object by range.

In the code snippets below, `x` is a Seqinfo object.

#### `as(x, "GRanges")`, `as(x, "GenomicRanges")`, `as(x, "RangesList")`:
Turns Seqinfo object `x` (with no NA lengths) into a GRanges or RangesList.
In the following code snippets, x is a GRanges object.

**length(x):** Get the number of elements.

**seqnames(x), seqnames(x) <- value:** Get or set the sequence names. value can be an Rle object, a character vector, or a factor.

**ranges(x), ranges(x) <- value:** Get or set the ranges. value can be a Ranges object.

**names(x), names(x) <- value:** Get or set the names of the elements.

**strand(x), strand(x) <- value:** Get or set the strand. value can be an Rle object, character vector, or factor.

**mcols(x, use.names=FALSE), mcols(x) <- value:** Get or set the metadata columns. If use.names=TRUE and the metadata columns are not NULL, then the names of x are propagated as the row names of the returned DataFrame object. When setting the metadata columns, the supplied value must be NULL or a data.frame-like object (i.e. DataTable or data.frame) object holding element-wise metadata.

**elementMetadata(x), elementMetadata(x) <- value, values(x), values(x) <- value:** Alternatives to mcols functions. Their use is discouraged.

**seqinfo(x), seqinfo(x) <- value:** Get or set the information about the underlying sequences. value must be a Seqinfo object.

**seqlevels(x), seqlevels(x, force=FALSE) <- value:** Get or set the sequence levels. seqlevels(x) is equivalent to seqlevels(seqinfo(x)) or to levels(seqnames(x)), those 2 expressions being guaranteed to return identical character vectors on a GRanges object. value must be a character vector with no NAs. See ?seqlevels for more information.

**seqlengths(x), seqlengths(x) <- value:** Get or set the sequence lengths. seqlengths(x) is equivalent to seqlengths(seqinfo(x)). value can be a named non-negative integer or numeric vector eventually with NAs.

**isCircular(x), isCircular(x) <- value:** Get or set the circularity flags. isCircular(x) is equivalent to isCircular(seqinfo(x)). value must be a named logical vector eventually with NAs.

**genome(x), genome(x) <- value:** Get or set the genome identifier or assembly name for each sequence. genome(x) is equivalent to genome(seqinfo(x)). value must be a named character vector eventually with NAs.

**seqlevelsStyle(x), seqlevelsStyle(x) <- value:** Get or set the seqname style for x. See the seqlevelsStyle generic getter and setter in the GenomeInfoDb package for more information.

**score(x), score(x) <- value:** Get or set the “score” column from the element metadata.

**granges(x, use.mcols=FALSE):** Gets a GRanges with only the range information from x, unless use.mcols is TRUE, in which case the metadata columns are also returned. Those columns will include any “extra column slots” if x is a specialized GenomicRanges derivative.

### Ranges methods

In the following code snippets, x is a GRanges object.

**start(x), start(x) <- value:** Get or set start(ranges(x)).

**end(x), end(x) <- value:** Get or set end(ranges(x)).

**width(x), width(x) <- value:** Get or set width(ranges(x)).
GRanges-class

Splitting and Combining

In the code snippets below, x is a GRanges object.

append(x, values, after = length(x)): Inserts the values into x at the position given by after, where x and values are of the same class.

c(x, ...): Combines x and the GRanges objects in ... together. Any object in ... must belong to the same class as x, or to one of its subclasses, or must be NULL. The result is an object of the same class as x.

c(x, ..., ignore.mcols=FALSE) If the GRanges objects have metadata columns (represented as one DataFrame per object), each such DataFrame must have the same columns in order to combine successfully. In order to circumvent this restraint, you can pass in an ignore.mcols=TRUE argument which will combine all the objects into one and drop all of their metadata columns.

split(x, f, drop=FALSE): Splits x according to f to create a GRangesList object. If f is a list-like object then drop is ignored and f is treated as if it was rep(seq_len(length(f)), sapply(f, length)), so the returned object has the same shape as f (it also receives the names of f). Otherwise, if f is not a list-like object, empty list elements are removed from the returned object if drop is TRUE.

Subsetting

In the code snippets below, x is a GRanges object.

x[i, j], x[i, j] <- value: Get or set elements i with optional metadata columns mcols(x)[, j], where i can be missing: an NA-free logical, numeric, or character vector; or a 'logical' Rle object.

x[i, j] <- value: Replaces elements i and optional metadata columns j with value.

head(x, n = 6L): If n is non-negative, returns the first n elements of the GRanges object. If n is negative, returns all but the last abs(n) elements of the GRanges object.

rep(x, times, length.out, each): Repeats the values in x through one of the following conventions:

times Vector giving the number of times to repeat each element if of length length(x), or to repeat the whole vector if of length 1.

length.out Non-negative integer. The desired length of the output vector.

each Non-negative integer. Each element of x is repeated each times.

subset(x, subset): Returns a new object of the same class as x made of the subset using logical vector subset, where missing values are taken as FALSE.

tail(x, n = 6L): If n is non-negative, returns the last n elements of the GRanges object. If n is negative, returns all but the first abs(n) elements of the GRanges object.

window(x, start = NA, end = NA, width = NA, frequency = NULL, delta = NULL, ...): Extracts the subsequence window from the GRanges object using:

start, end, width The start, end, or width of the window. Two of the three are required.

frequency, delta Optional arguments that specify the sampling frequency and increment within the window.

In general, this is more efficient than using "[" operator.

window(x, start = NA, end = NA, width = NA, keepLength = TRUE) <- value: Replaces the subsequence window specified on the left (i.e. the subsequence in x specified by start, end and width) by value. value must either be of class class(x), belong to a subclass of class(x), be coercible to class(x), or be NULL. If keepLength is TRUE, the elements of
value are repeated to create a GRanges object with the same number of elements as the width of the subsequence window it is replacing. If `keepLength` is `FALSE`, this replacement method can modify the length of `x`, depending on how the length of the left subsequence window compares to the length of `value`.

```r
x$name, x$name <- value: Shortcuts for `mcols(x)$name` and `mcols(x)$name <- value`, respectively. Provided as a convenience, for GRanges objects *only*, and as the result of strong popular demand. Note that those methods are not consistent with the other `$` and `$<-` methods in the IRanges/GenomicRanges infrastructure, and might confuse some users by making them believe that a GRanges object can be manipulated as a data.frame-like object. Therefore we recommend using them only interactively, and we discourage their use in scripts or packages. For the latter, use `mcols(x)$name` and `mcols(x)$name <- value`, instead of `x$name` and `x$name <- value`, respectively.

Note that a GRanges object can be used to as a subscript to subset a list-like object that has names on it. In that case, the names on the list-like object are interpreted as sequence names. In the code snippets below, `x` is a list or `List` object with names on it, and the subscript `gr` is a GRanges object with all its seqnames being valid `x` names.

```r
x[gr]: Return an object of the same class as `x` and `parallel` to `gr`. More precisely, it’s conceptually doing:

```r
lapply(gr, function(gr1) x[[seqnames(gr1)]][ranges(gr1)])
```

### Other methods

`show(x)`: By default the `show` method displays 5 head and 5 tail elements. This can be changed by setting the global options `showHeadLines` and `showTailLines`. If the object length is less than (or equal to) the sum of these 2 options plus 1, then the full object is displayed. Note that these options also affect the display of `GAlignments` and `GAlignmentPairs` objects (defined in the `GenomicAlignments` package), as well as other objects defined in the `IRanges` and `Biostrings` packages (e.g. `IRanges` and `DNAStringSet` objects).

### See Also

- `makeGRangesFromDataFrame` for making a GRanges object from a data.frame or `DataFrame` object.
- `seqinfo` for accessing/modifying information about the underlying sequences of a GRanges object.
- The `GPos` class, a memory-efficient container for storing genomic *positions*, that is, genomic ranges of width 1.
- `GenomicRanges-comparison` for comparing and ordering genomic ranges.
- `findOverlaps-methods` for finding/counting overlapping genomic ranges.
- `intra-range-methods` and `inter-range-methods` for intra range and inter range transformations of a GRanges object.
- `coverage-methods` for computing the coverage of a GRanges object.
- `setops-methods` for set operations on GRanges objects.
- `nearest-methods` for finding the nearest genomic range neighbor.
• **absoluteRanges** for transforming genomic ranges into *absolute* ranges (i.e. into ranges on the sequence obtained by virtually concatenating all the sequences in a genome).

• **tileGenome** for putting tiles on a genome.

• **genomicvars** for manipulating genomic variables.

• **GRangesList** objects.

• **Ranges** objects in the **IRanges** package.

• **Vector**, **Rle**, and **DataFrame** objects in the **S4Vectors** package.

### Examples

```r
## CONSTRUCTION

## Specifying the bare minimum i.e. seqnames and ranges only. The GRanges object will have no names, no strand information, and no metadata columns:
gr0 <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)), IRanges(1:10, width=10:1))
gr0

## Specifying names, strand, metadata columns. They can be set on an existing object:
names(gr0) <- head(letters, 10)
strand(gr0) <- Rle(strand(c("-", "+", "+", "+", "-")), c(1, 2, 2, 3, 2))
mcols(gr0)$score <- 1:10
mcols(gr0)$GC <- seq(1, 0, length=10)
gr0

## ... or specified at construction time:
gr <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
IRanges(1:10, width=10:1, names=head(letters, 10)),
Rle(strand(c("-", "+", "+", "+", "-")), c(1, 2, 2, 3, 2)),
score=1:10, GC=seq(1, 0, length=10))
stopifnot(identical(gr0, gr))

## Specifying the seqinfo. It can be set on an existing object:
seqinfo <- Seqinfo(paste0("chr", 1:3), c(1000, 2000, 1500), NA, "mock1")
seqinfo(gr0) <- merge(seqinfo(gr0), seqinfo)
seqlevels(gr0) <- seqlevels(seqinfo)

## ... or specified at construction time:
gr <- GRanges(Rle(c("chr2", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
IRanges(1:10, width=10:1, names=head(letters, 10)),
Rle(strand(c("-", "+", "+", "+", "-")), c(1, 2, 2, 3, 2)),
score=1:10, GC=seq(1, 0, length=10),
seqinfo=seqinfo)
stopifnot(identical(gr0, gr))

## COERCION

## From GRanges:
as.character(gr)
as.factor(gr)
as.data.frame(gr)
```
## From character to GRanges:
x1 <- "chr2:56-125"
as(x1, "GRanges")
as(rep(x1, 4), "GRanges")
x2 <- c(A=x1, B="chr1:25-30:-")
as(x2, "GRanges")

## From data.frame to GRanges:
df <- data.frame(chrom="chr2", start=11:15, end=20:24)
gr3 <- as(df, "GRanges")

## Alternatively, coercion to GRanges can be done by just calling the
## GRanges() constructor on the object to coerce:
gr1 <- GRanges(x1)  # same as as(x1, "GRanges")
gr2 <- GRanges(x2)  # same as as(x2, "GRanges")
gr3 <- GRanges(df)  # same as as(df, "GRanges")

## Sanity checks:
stopifnot(identical(as(x1, "GRanges"), gr1))
stopifnot(identical(as(x2, "GRanges"), gr2))
stopifnot(identical(as(df, "GRanges"), gr3))

## SUMMARIZING ELEMENTS

### table(seqnames(gr))
table(strand(gr))
sum(width(gr))
table(gr)
table(mcols(gr)[,"score"])

## The number of lines displayed in the 'show' method are controlled
## with two global options:
longGR <- sample(gr, 25, replace=TRUE)
longGR
options(showHeadLines=7)
options(showTailLines=2)
longGR

## Revert to default values
options(showHeadLines=NULL)
options(showTailLines=NULL)

## INVERTING THE STRAND

### invertStrand(gr)

## RENAMING THE UNDERLYING SEQUENCES

### seqlevels(gr)
seqlevels(gr) <- sub("chr", "Chrom", seqlevels(gr))
gr
seqlevels(gr) <- sub("Chrom", "chr", seqlevels(gr))  # revert
### COMBINING OBJECTS

```r
gr2 <- GRanges(seqnames=Rle(c('chr1', 'chr2', 'chr3'), c(3, 3, 4)),
               IRanges(1:10, width=5),
               strand='-',
               score=101:110, GC=runif(10),
               seqinfo=seqinfo)

gr3 <- GRanges(seqnames=Rle(c('chr1', 'chr2', 'chr3'), c(3, 4, 3)),
               IRanges(101:110, width=10),
               strand='-',
               score=21:30,
               seqinfo=seqinfo)

some.gr <- c(gr, gr2)

all.gr <- c(gr, gr2, gr3, ignore.mcols=TRUE)
```

### USING A GRANGES OBJECT AS A SUBSCRIPT TO SUBSET ANOTHER OBJECT

```r
x <- RleList(chr1=101:120, chr2=2:-8, chr3=31:40)
x[gr]
```
ranges(x, use.mcols=FALSE), ranges(x) <- value: Get or set the ranges in the form of a CompressedIRangesList. value can be a RangesList object.

start(x), start(x) <- value: Get or set start(ranges(x)).

dend(x), end(x) <- value: Get or set end(ranges(x)).

width(x), width(x) <- value: Get or set width(ranges(x)).

strand(x), strand(x) <- value: Get or set the strand in the form of an RleList. value can be an RleList, CharacterList or single character. value as a single character converts all ranges in x to the same value; for selective strand conversion (i.e., mixed “+” and “-”) use RleList or CharacterList.

mcols(x, use.names=FALSE), mcols(x) <- value: Get or set the metadata columns. value can be NULL, or a data.frame-like object (i.e. DataFrame or data.frame) holding element-wise metadata.

elementMetadata(x), elementMetadata(x) <- value, values(x), values(x) <- value: Alternatives to mcols functions. Their use is discouraged.

seqinfo(x), seqinfo(x) <- value: Get or set the information about the underlying sequences. value must be a Seqinfo object.

seqlevels(x), seqlevels(x, force=FALSE) <- value: Get or set the sequence levels. seqlevels(x) is equivalent to seqlevels(seqinfo(x)) or to levels(seqnames(x)), those 2 expressions being guaranteed to return identical character vectors on a GRangesList object. value must be a character vector with no NAs. See ?seqlevels for more information.

seqlengths(x), seqlengths(x) <- value: Get or set the sequence lengths. seqlengths(x) is equivalent to seqlengths(seqinfo(x)). value can be a named non-negative integer or numeric vector eventually with NAs.

isCircular(x), isCircular(x) <- value: Get or set the circularity flags. isCircular(x) is equivalent to isCircular(seqinfo(x)). value must be a named logical vector eventually with NAs.

geno(x), genome(x) <- value: Get or set the genome identifier or assembly name for each sequence. genome(x) is equivalent to genome(seqinfo(x)). value must be a named character vector eventually with NAs.

seqlevelsStyle(x), seqlevelsStyle(x) <- value: Get or set the seqname style for x. See the seqlevelsStyle generic getter and setter in the GenomeInfoDb package for more information.

score(x), score(x) <- value: Get or set the “score” metadata column.

Coercion

In the code snippets below, x is a GRangesList object.

as.data.frame(x, row.names = NULL, optional = FALSE, ..., value.name = “value”, use.outer.mcols = FALSE): Coerces x to a data.frame. See as.data.frame on the List man page for details (?List).

as.list(x, use.names = TRUE): Creates a list containing the elements of x.

as(x, "IRangesList"): Turns x into an IRangesList object.

as(from, "GRangesList"): Creates a GRangesList object from a RangedDataList object.

Subsetting

In the following code snippets, x is a GRangesList object.
x[i, j].x[i, j] <- value: Get or set elements i with optional metadata columns mcols(x)[i, j], where i can be missing; an NA-free logical, numeric, or character vector; a 'logical' Rle object, or an AtomicList object.

x[[i]], x[[i]] <- value: Get or set element i, where i is a numeric or character vector of length 1.

x$name, x$name <- value: Get or set element name, where name is a name or character vector of length 1.

head(x, n = 6L): If n is non-negative, returns the first n elements of the GRangesList object. If n is negative, returns all but the last abs(n) elements of the GRangesList object.

rep(x, times, length.out, each): Repeats the values in x through one of the following conventions:

- times: Vector giving the number of times to repeat each element if of length length(x), or to repeat the whole vector if of length 1.
- length.out: Non-negative integer. The desired length of the output vector.
- each: Non-negative integer. Each element of x is repeated each times.

subset(x, subset): Returns a new object of the same class as x made of the subset using logical vector subset, where missing values are taken as FALSE.

tail(x, n = 6L): If n is non-negative, returns the last n elements of the GRanges object. If n is negative, returns all but the first abs(n) elements of the GRanges object.

Combining

In the code snippets below, x is a GRangesList object.

c(x, ...): Combines x and the GRangesList objects in ... together. Any object in ... must belong to the same class as x, or to one of its subclasses, or must be NULL. The result is an object of the same class as x.

append(x, values, after = length(x)): Inserts the values into x at the position given by after, where x and values are of the same class.

unlist(x, recursive = TRUE, use.names = TRUE): Concatenates the elements of x into a single GRanges object.

Looping

In the code snippets below, x is a GRangesList object.

endoapply(X, FUN, ...): Similar to lapply, but performs an endomorphism, i.e. returns an object of class(X).

lapply(X, FUN, ...): Like the standard lapply function defined in the base package, the lapply method for GRangesList objects returns a list of the same length as X, with each element being the result of applying FUN to the corresponding element of X.

Map(f, ...): Applies a function to the corresponding elements of given GRangesList objects.

mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE): Like the standard mapply function defined in the base package, the mapply method for GRangesList objects is a multivariate version of sapply.

mendoapply(FUN, ..., MoreArgs = NULL): Similar to mapply, but performs an endomorphism across multiple objects, i.e. returns an object of class(list(...)[[1]]).

Reduce(f, x, init, right = FALSE, accumulate = FALSE): Uses a binary function to successively combine the elements of x and a possibly given initial value.
f  A binary argument function.
init  An R object of the same kind as the elements of x.
right  A logical indicating whether to proceed from left to right (default) or from right to left.
nomatch  The value to be returned in the case when “no match” (no element satisfying the
predicate) is found.

sapply(X, FUN, ..., simplify=TRUE, USE.NAMES=TRUE): Like the standard sapply function
defined in the base package, the sapply method for GRangesList objects is a user-friendly
version of lapply by default returning a vector or matrix if appropriate.

inter-range-methods  Inter range transformations of a GRanges or GRangesList object

Usage

```
## S4 method for signature 'GenomicRanges'
range(x, ..., ignore.strand=FALSE, na.rm=FALSE)
## S4 method for signature 'GRangesList'
range(x, ..., ignore.strand=FALSE, na.rm=FALSE)

## S4 method for signature 'GenomicRanges'
reduce(x, drop.empty.ranges=FALSE, min.gapwidth=1L, with.revmap=FALSE,
    with.inframe.attrib=FALSE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
reduce(x, drop.empty.ranges=FALSE, min.gapwidth=1L, with.revmap=FALSE,
    with.inframe.attrib=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
gaps(x, start=1L, end=seqlengths(x))

## S4 method for signature 'GenomicRanges'
disjoin(x, with.revmap=FALSE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
disjoin(x, with.revmap=FALSE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
isDisjoint(x, ignore.strand=FALSE)
```
## S4 method for signature 'GRangesList'

isDisjoint(x, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'

disjointBins(x, ignore.strand=FALSE)

### Arguments

- **x**
  - A GenomicRanges object.

- **drop.empty.ranges**, **min.gapwidth**, **with.revmap**, **with.inframe.attrib**, **start**, **end**
  - See ?`inter-range-methods` in the IRanges package.

- **ignore.strand**
  - TRUE or FALSE. Whether the strand of the input ranges should be ignored or not. See details below.

- **...**
  - For range, additional GenomicRanges objects to consider. Ignored otherwise.

- **na.rm**
  - Ignored.

### Details

**On a GRanges object:** range returns an object of the same type as x containing range bounds for each distinct (seqname, strand) pairing. The names (names(x)) and the metadata columns in x are dropped.

reduce returns an object of the same type as x containing reduced ranges for each distinct (seqname, strand) pairing. The names (names(x)) and the metadata columns in x are dropped. See ?reduce for more information about range reduction and for a description of the optional arguments.

gaps returns an object of the same type as x containing complemented ranges for each distinct (seqname, strand) pairing. The names (names(x)) and the columns in x are dropped. For the start and end arguments of this gaps method, it is expected that the user will supply a named integer vector (where the names correspond to the appropriate seqlevels). See ?gaps for more information about range complements and for a description of the optional arguments.

disjoin returns an object of the same type as x containing disjoint ranges for each distinct (seqname, strand) pairing. The names (names(x)) and the metadata columns in x are dropped. If with.revmap=TRUE, a metadata column that maps the output ranges to the input ranges is added to the returned object. See ?disjoin for more information.

isDisjoint returns a logical value indicating whether the ranges in x are disjoint (i.e. non-overlapping).

disjointBins returns bin indexes for the ranges in x, such that ranges in the same bin do not overlap. If ignore.strand=FALSE, the two features cannot overlap if they are on different strands.

**On a GRangesList object:** When they are supported on GRangesList object x, the above inter-range transformations will apply the transformation to each of the list elements in x and return a list-like object parallel to x (i.e. with 1 list element per list element in x). If x has names on it, they’re propagated to the returned object.

Intra range transformations of a GRanges or GRangesList object

Description

This man page documents intra range transformations of a GenomicRanges object (i.e. of an object that belongs to the GenomicRanges class or one of its subclasses, this includes for example GRanges objects), or a GRangesList object.

See '?intra-range-methods' and '?inter-range-methods' in the IRanges package for a quick introduction to intra range and inter range transformations.

Intra range methods for GAlignments and GAlignmentsList objects are defined and documented in the GenomicAlignments package.

See '?inter-range-methods' for inter range transformations of a GenomicRanges or GRangesList object.

Usage

```r
## S4 method for signature 'GenomicRanges'
shift(x, shift=0L, use.names=TRUE)
## S4 method for signature 'GRangesList'
shift(x, shift=0L, use.names=TRUE)

## S4 method for signature 'GenomicRanges'
narrow(x, start=NA, end=NA, width=NA, use.names=TRUE)
## S4 method for signature 'GRangesList'
narrow(x, start=NA, end=NA, width=NA, use.names=TRUE)

## S4 method for signature 'GenomicRanges'
resize(x, width, fix="start", use.names=TRUE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
resize(x, width, fix="start", use.names=TRUE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
flank(x, width, start=TRUE, both=FALSE, use.names=TRUE, ignore.strand=FALSE)
## S4 method for signature 'GRangesList'
flank(x, width, start=TRUE, both=FALSE, use.names=TRUE, ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges'
promoters(x, upstream=2000, downstream=200, ...)
## S4 method for signature 'GRangesList'
promoters(x, upstream=2000, downstream=200, ...)

## S4 method for signature 'GenomicRanges'
restrict(x, start=NA, end=NA, keep.all.ranges=FALSE, use.names=TRUE)
## S4 method for signature 'GRangesList'
restrict(x, start=NA, end=NA, keep.all.ranges=FALSE, use.names=TRUE)
```
## S4 method for signature 'GenomicRanges'

trim(x, use.names=TRUE)

**Arguments**

- **x**: A **GenomicRanges** or **GRangesList** object.
- **shift**, **use.names**, **start**, **end**, **width**, **both**, **fix**, **keep.all.ranges**, **upstream**, **downstream**
  See `?intra-range-methods`.
- **ignore.strand**: **TRUE** or **FALSE**. Whether the strand of the input ranges should be ignored or not. See details below.
- **...**: Additional arguments to methods.

**Details**

- **shift** behaves like the shift method for **Ranges** objects. See `?intra-range-methods` for the details.
- **()narrow** on a **GenomicRanges** object behaves like on a **Ranges** object. See `?intra-range-methods` for the details.
  A major difference though is that it returns a **GenomicRanges** object instead of a **Ranges** object. The returned object is *parallel* (i.e. same length and names) to the original object x.
- **resize** returns an object of the same type and length as x containing intervals that have been resized to width based on the strand(x) values. Elements where strand(x) == "+" or strand(x) == "*" are anchored at start(x) and elements where strand(x) == "-" are anchored at the end(x). The use.names argument determines whether or not to keep the names on the ranges.
- **flank** returns an object of the same type and length as x containing intervals of width width that flank the intervals in x. The start argument takes a logical indicating whether x should be flanked at the "start" (TRUE) or the "end" (FALSE), which for strand(x) != "-" is start(x) and end(x) respectively and for strand(x) == "-" are anchored at the end(x). The both argument takes a single logical value indicating whether the flanking region width positions extends into the range. If both=TRUE, the resulting range thus straddles the end point, with width positions on either side.
- **promoters** returns an object of the same type and length as x containing promoter ranges. Promoter ranges extend around the transcription start site (TSS) which is defined as start(x). The upstream and downstream arguments define the number of nucleotides in the 5' and 3' direction, respectively. The full range is defined as, (start(x) - upstream) to (start(x) + downstream - 1).
  Ranges on the * strand are treated the same as those on the + strand. When no seqlengths are present in x, it is possible to have non-positive start values in the promoter ranges. This occurs when (TSS - upstream) < 1. In the equal but opposite case, the end values of the ranges may extend beyond the chromosome end when (TSS + downstream + 1) > 'chromosome end'. When seqlengths are not NA the promoter ranges are kept within the bounds of the defined seqlengths.
- **restrict** returns an object of the same type and length as x containing restricted ranges for distinct seqnames. The start and end arguments can be a named numeric vector of seqnames for the ranges to be restricted or a numeric vector or length 1 if the restriction operation is to be applied to all the sequences in x. See `?intra-range-methods` for more information about range restriction and for a description of the optional arguments.
- **trim** trims out-of-bound ranges located on non-circular sequences whose length is not NA.
`makeGRangesFromDataFrame`  

Make a GRanges object from a data.frame or DataFrame

gr3 <- GRanges(c("chr1", "chr2"), IRanges(c(1, 4), c(3, 9)),
               strand="-")
gr1 <- GRangesList(gr1= gr1, gr2=gr2, gr3=gr3)
grl

resize(grl, width=20)
flank(grl, width=20)
restrict(grl, start=3)
```

`makeGRangesFromDataFrame`
**Description**

*makeGRangesFromDataFrame* takes a data-frame-like object as input and tries to automatically find the columns that describe genomic ranges. It returns them as a *GRanges* object.

*makeGRangesFromDataFrame* is also the workhorse behind the coercion method from *data.frame* (or *DataFrame*) to *GRanges*.

**Usage**

```r
call.makeGRangesFromDataFrame(df, 
    keep.extra.columns=FALSE, 
    ignore.strand=FALSE, 
    seqinfo=NULL, 
    seqnames.field=c("seqnames", "seqname", 
                      "chromosome", "chrom", 
                      "chr", "chromosome_name", 
                      "seqid"), 
    start.field="start", 
    end.field=c("end", "stop"), 
    strand.field="strand", 
    starts.in.df.are.0based=FALSE)
```

**Arguments**

- **df**: A *data.frame* or *DataFrame* object. If not, then the function first tries to turn *df* into a data frame with `as.data.frame(df)`.
- **keep.extra.columns**: TRUE or FALSE (the default). If TRUE, the columns in *df* that are not used to form the genomic ranges of the returned *GRanges* object are then returned as metadata columns on the object. Otherwise, they are ignored. If *df* has a width column, then it’s always ignored.
- **ignore.strand**: TRUE or FALSE (the default). If TRUE, then the strand of the returned *GRanges* object is set to "*".
- **seqinfo**: Either NULL, or a *Seqinfo* object, or a character vector of seqlevels, or a named numeric vector of sequence lengths. When not NULL, it must be compatible with the genomic ranges in *df* i.e. it must include at least the sequence levels represented in *df*.
- **seqnames.field**: A character vector of recognized names for the column in *df* that contains the chromosome name (a.k.a. sequence name) associated with each genomic range. Only the first name in *seqnames.field* that is found in *colnames(df)* is used. If no one is found, then an error is raised.
- **start.field**: A character vector of recognized names for the column in *df* that contains the start positions of the genomic ranges. Only the first name in *start.field* that is found in *colnames(df)* is used. If no one is found, then an error is raised.
- **end.field**: A character vector of recognized names for the column in *df* that contains the end positions of the genomic ranges. Only the first name in *start.field* that is found in *colnames(df)* is used. If no one is found, then an error is raised.
- **strand.field**: A character vector of recognized names for the column in *df* that contains the strand associated with each genomic range. Only the first name in *strand.field* that is found in *colnames(df)* is used. If no one is found or if *ignore.strand* is TRUE, then the strand of the returned *GRanges* object is set to "*".
starts.in.df.are.0based
TRUE or FALSE (the default). If TRUE, then the start positions of the genomic ranges in df are considered to be 0-based and are converted to 1-based in the returned GRanges object. This feature is intended to make it more convenient to handle input that contains data obtained from resources using the "0-based start" convention. A notorious example of such resource is the UCSC Table Browser (http://genome.ucsc.edu/cgi-bin/hgTables).

Value
A GRanges object with one element per row in the input.

If the seqinfo argument was supplied, the returned object will have exactly the seqlevels specified in seqinfo and in the same order. Otherwise, the seqlevels are ordered according to the output of the rankSeqlevels function (except if df contains the seqnames in the form of a factor-Rle, in which case the levels of the factor-Rle become the seqlevels of the returned object and with no re-ordering).

If df has non-automatic row names (i.e. rownames(df) is not NULL and is not seq_len(nrow(df))), then they will be used to set names on the returned GRanges object.

Note
Coercing data.frame or DataFrame df into a GRanges object (with as(df, "GRanges"), or calling GRanges(df), are both equivalent to calling makeGRangesFromDataFrame(df, keep.extra.columns=TRUE).

makeGRangesFromDataFrame(df, seqinfo=Seqinfo(paste0("chr", 4:1)))

## ---------------------------------------------------------------------
## ABOUT AUTOMATIC DETECTION OF THE seqnames/start/end/strand COLUMNS
## ---------------------------------------------------------------------

## Automatic detection of the seqnames/start/end/strand columns is
## case insensitive:
df <- data.frame(ChRoM="chr1", StarT=11:15, stoP=12:16,
                 STRAND=c("+","-","+","\*","-"), score=1:5)
makeGRangesFromDataFrame(df)

## It also ignores a common prefix between the start and end columns:
df <- data.frame(seqnames="chr1", tx_start=11:15, tx_end=12:16,
                 strand=c("+","-","+","\*","-"), score=1:5)
makeGRangesFromDataFrame(df)

## The common prefix between the start and end columns is used to
## disambiguate between more than one seqnames column:
df <- data.frame(chrom="chr1", tx_start=11:15, tx_end=12:16,
                 tx_chr="chr2", score=1:5)
makeGRangesFromDataFrame(df)

## ---------------------------------------------------------------------
## 0-BASED VS 1-BASED START POSITIONS
## ---------------------------------------------------------------------

if (require(rtracklayer)) {
  session <- browserSession()
genome(session) <- "sacCer2"
query <- ucscTableQuery(session, "Most Conserved")
df <- getTable(query)

## A common pitfall is to forget that the UCSC Table Browser uses the
## "0-based start" convention:
gr0 <- makeGRangesFromDataFrame(df, keep.extra.columns=TRUE)
head(gr0)
min(start(gr0))

## The start positions need to be converted into 1-based positions,
## to adhere to the convention used in Bioconductor:
gr1 <- makeGRangesFromDataFrame(df, keep.extra.columns=TRUE,
                                 starts.in.df.are.0based=TRUE)
head(gr1)
}
Make a GRangesList object from a data.frame or DataFrame

Description

makeGRangesListFromDataFrame extends the makeGRangesFromDataFrame functionality from GenomicRanges. It can take a data-frame-like object as input and tries to automatically find the columns that describe the genomic ranges. It returns a GRangesList object. This is different from the makeGRangesFromDataFrame function by requiring a split.field. The split.field acts like the "f" argument in the split function. This factor must be of the same length as the number of rows in the DataFrame argument. The split.field may also be a character vector.

Usage

makeGRangesListFromDataFrame(df, 
    split.field = NULL, 
    names.field = NULL, 
    ...)

Arguments

df  A DataFrame or data.frame class object
split.field  A character string of a recognized column name in df that contains the grouping. This column defines how the rows of df are split and is typically a factor or character vector. When split.field is not provided the df will be split by the number of rows.
names.field  An optional single character string indicating the name of the column in df that designates the names for the ranges in the elements of the GRangesList.
...
Additional arguments passed on to makeGRangesFromDataFrame

Value

A GRangesList of the same length as the number of levels or unique character strings in the df column indicated by split.field. When split.field is not provided the df is split by row and the resulting GRangesList has the same length as nrow(df).

Names on the individual ranges are taken from the names.field argument. Names on the outer list elements of the GRangesList are propagated from split.field.

nearest-methods

Finding the nearest genomic range neighbor

Description

The nearest, precede, follow, distance and distanceToNearest methods for GenomicRanges objects and subclasses.

Usage

```r
## S4 method for signature 'GenomicRanges,GenomicRanges'
precede(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
precede(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
follow(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
follow(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
nearest(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)
## S4 method for signature 'GenomicRanges,missing'
nearest(x, subject, select=c("arbitrary", "all"), ignore.strand=FALSE)

## S4 method for signature 'GenomicRanges,GenomicRanges'
distanceToNearest(x, subject, ignore.strand=FALSE, ...)
## S4 method for signature 'GenomicRanges,missing'
distanceToNearest(x, subject, ignore.strand=FALSE, ...)

## S4 method for signature 'GenomicRanges,GenomicRanges'
distance(x, y, ignore.strand=FALSE, ...)
```
nearest-methods

Arguments

- **x**: The query GenomicRanges instance.
- **subject**: The subject GenomicRanges instance within which the nearest neighbors are found. Can be missing, in which case x is also the subject.
- **y**: For the distance method, a GRanges instance. Cannot be missing. If x and y are not the same length, the shortest will be recycled to match the length of the longest.
- **select**: Logic for handling ties. By default, all methods select a single interval (arbitrary for nearest, the first by order in subject for precede, and the last for follow). When select="all" a Hits object is returned with all matches for x. If x does not have a match in subject the x is not included in the Hits object.
- **ignore.strand**: A logical indicating if the strand of the input ranges should be ignored. When TRUE, strand is set to '+/Var+/Var+.'
- **...**: Additional arguments for methods.

Details

- **nearest**: Performs conventional nearest neighbor finding. Returns an integer vector containing the index of the nearest neighbor range in subject for each range in x. If there is no nearest neighbor NA is returned. For details of the algorithm see the man page in IRanges, ?nearest.
- **precede**: For each range in x, precede returns the index of the range in subject that is directly preceded by the range in x. Overlapping ranges are excluded. NA is returned when there are no qualifying ranges in subject.
- **follow**: The opposite of precede, follow returns the index of the range in subject that is directly followed by the range in x. Overlapping ranges are excluded. NA is returned when there are no qualifying ranges in subject.
- **Orientation and Strand**: The relevant orientation for precede and follow is 5’ to 3’, consistent with the direction of translation. Because positional numbering along a chromosome is from left to right and transcription takes place from 5’ to 3’, precede and follow can appear to have ‘opposite’ behavior on the + and - strand. Using positions 5 and 6 as an example, 5 precedes 6 on the + strand but follows 6 on the - strand.

Below we outline the priority when ranges on multiple strands are compared. Ranges of strand * treat all ranges as if on the + strand; this is the behavior as ignore.strand=TRUE.

- x on + strand can match to ranges on both + and * strands. In the case of a tie the first range by order is chosen.
- x on - strand can match to ranges on both - and * strands. In the case of a tie the first range by order is chosen.
- x on * treats all ranges as if on the + strand. In the case of a tie the first range by order is chosen.

- **distanceToNearest**: Returns the distance for each range in x to its nearest neighbor in the subject.
- **distance**: Returns the distance for each range in x to the range in y. The behavior of distance has changed in Bioconductor 2.12. See the man page ?distance in IRanges for details.

Value

For nearest, precede and follow, an integer vector of indices in subject, or a Hits if select="all".
For distanceToNearest, a Hits object with a column for the query index (queryHits), subject index (subjectHits) and the distance between the pair.
For distance, an integer vector of distances between the ranges in x and y.

Examples

## -----------------------------------------------------------
## precede() and follow()
## -----------------------------------------------------------
query <- GRanges("A", IRanges(c(5, 20), width=1), strand="+")
subject <- GRanges("A", IRanges(rep(c(10, 15), 2), width=1),
  strand=c("+", "+", "-", "+\n1"))
precede(query, subject)
follow(query, subject)

strand(query) <- "-"
precede(query, subject)
follow(query, subject)

## ties choose first in order
query <- GRanges("A", IRanges(10, width=1), c("+", "-", "+\n1"))
subject <- GRanges("A", IRanges(rep(c(5, 5, 15, 15, 15), width=1),
  rep(c("+", "-", "+\n1"), 2))
precede(query, subject)
predce(query, rev(subject))

## ignore.strand=TRUE treats all ranges as '+'
predce(query[1], subject[4:6], select="all", ignore.strand=FALSE)
predce(query[1], subject[4:6], select="all", ignore.strand=TRUE)

## nearest()
## -----------------------------------------------------------
## When multiple ranges overlap an "arbitrary" range is chosen
query <- GRanges("A", IRanges(5, 15))
subject <- GRanges("A", IRanges(c(1, 15), c(5, 19)))
nearest(query, subject)

## select="all" returns all hits
nearest(query, subject, select="all")

## Ranges in 'x' will self-select when 'subject' is present
query <- GRanges("A", IRanges(c(1, 10), width=5))
nearest(query, query)

## Ranges in 'x' will not self-select when 'subject' is missing
phicoef

Calculate the "phi coefficient" between two binary variables

**Description**

The `phicoef` function calculates the "phi coefficient" between two binary variables.

**Usage**

```r
phicoef(x, y=NULL)
```

**Arguments**

- `x, y`
  
  Two logical vectors of the same length. If `y` is not supplied, `x` must be a 2x2 integer matrix (or an integer vector of length 4) representing the contingency table of two binary variables.

**Value**

The "phi coefficient" between the two binary variables. This is a single numeric value ranging from -1 to +1.

**Author(s)**

H. Pagès

**References**

range-squeezer

Squeeze the ranges out of a range-based object

Description

S4 generic functions for squeezing the ranges out of a range-based object. granges returns them in a GRanges object, grglist in a GRangesList object, and rglist in a RangesList object.

Usage

granges(x, use.names=TRUE, use.mcols=FALSE, ...)  
grglist(x, use.names=TRUE, use.mcols=FALSE, ...)  
rglist(x, use.names=TRUE, use.mcols=FALSE, ...)

Arguments

x  A range-based object e.g. a RangedSummarizedExperiment, GAlignments, GAlignmentPairs, GAlignmentsList or a Pairs object containing ranges.

use.names  TRUE (the default) or FALSE. Whether or not the names on x (accessible with names(x)) should be propagated to the returned object.

use.mcols  TRUE or FALSE (the default). Whether or not the metadata columns on x (accessible with mcols(x)) should be propagated to the returned object.

...  Additional arguments, for use in specific methods.

Details

The GenomicRanges, SummarizedExperiment, and GenomicAlignments packages define and document methods for various types of range-based objects (e.g. for RangedSummarizedExperiment, GAlignments, GAlignmentPairs, and GAlignmentsList objects). Other Bioconductor packages might as well.

Note that these functions can be seen as a specific kind of object getters as well as functions performing coercion.

For some objects (e.g. GAlignments and GAlignmentPairs objects defined in the GenomicAlignments package), as(x, "GRanges"), as(x, "GRangesList"), and as(x, "RangesList"), are equivalent to granges(x, use.names=TRUE, use.mcols=TRUE), grglist(x, use.names=TRUE, use.mcols=TRUE), and rglist(x, use.names=TRUE, use.mcols=TRUE), respectively.
Value

A GRanges object for granges.
A GRangesList object for grglist.
A RangesList object for rglist.

If \( x \) is a vector-like object (e.g. GAlignments), the returned object is expected to be parallel to \( x \), that is, the \( i \)-th element in the output corresponds to the \( i \)-th element in the input.

If use.names is TRUE, then the names on \( x \) (if any) are propagated to the returned object. If use.mcols is TRUE, then the metadata columns on \( x \) (if any) are propagated to the returned object.

Examples

## See ?GAlignments in the GenomicAlignments package for some
## examples.
## Element-wise (aka "parallel") set operations
## --------------------------------------------

### S4 method for signature 'GRanges,GRanges'
punion(x, y, fill.gap=FALSE, ignore.strand=FALSE)

### S4 method for signature 'GRanges,GRanges'
pintersect(x, y, drop.nohit.ranges=FALSE, ignore.strand=FALSE, strict.strand=FALSE)

### S4 method for signature 'GRanges,GRanges'
psetdiff(x, y, ignore.strand=FALSE)

**Arguments**

- **x, y**  
  For union, intersect, and setdiff: 2 `GenomicRanges` objects or 2 `GRangesList` objects.  
  For `punion` and `pintersect`: 2 `GRanges` objects, or 1 `GRanges` object and 1 `GRangesList` object.  
  For `psetdiff`: x must be a `GRanges` object and y can be a `GRanges` or `GRangesList` object.  
  For `pgap`: 2 `GRanges` objects.  
  In addition, for the `parallel` operations, x and y must be of equal length (i.e. `length(x) == length(y)`).

- **fill.gap**  
  Logical indicating whether or not to force a union by using the rule `start = min(start(x), start(y)), end = max(end(x), end(y))`.

- **ignore.strand**  
  For set operations: If set to TRUE, then the strand of x and y is set to "*" prior to any computation.  
  For parallel set operations: If set to TRUE, the strand information is ignored in the computation and the result has the strand information of x.

- **drop.nohit.ranges**  
  If TRUE then elements in x that don’t intersect with their corresponding element in y are removed from the result (so the returned object is no more parallel to the input).  
  If FALSE (the default) then nothing is removed and a hit metadata column is added to the returned object to indicate elements in x that intersect with the corresponding element in y. For those that don’t, the reported intersection is a zero-width range that has the same start as x.

- **strict.strand**  
  If set to FALSE (the default), features on the "*" strand are treated as occurring on both the "+" and "-" strand. If set to TRUE, the strand of intersecting elements must be strictly the same.

**Details**

The `pintersect` methods involving `GRanges` and/or `GRangesList` objects use the triplet (sequence name, range, strand) to determine the element by element intersection of features, where a strand value of "*" is treated as occurring on both the "+" and "-" strand (unless `strict.strand` is set to TRUE, in which case the strand of intersecting elements must be strictly the same).

The `psetdiff` methods involving `GRanges` and/or `GRangesList` objects use the triplet (sequence name, range, strand) to determine the element by element set difference of features, where a strand value of "*" is treated as occurring on both the "+" and "-" strand.
**setops-methods**

**Value**

For `union`, `intersect`, and `setdiff`: a `GRanges` object if `x` and `y` are `GenomicRanges` objects, and a `GRangesList` object if they are `GRangesList` objects.

For `punion` and `pintersect`: when `x` or `y` is not a `GRanges` object, an object of the same class as this non-`GRanges` object. Otherwise, a `GRanges` object.

For `psetdiff`: either a `GRanges` object when both `x` and `y` are `GRanges` objects, or a `GRangesList` object when `y` is a `GRangesList` object.

For `pgap`: a `GRanges` object.

**Examples**

```r
## A. SET OPERATIONS
x <- GRanges("chr1", IRanges(c(2, 9), c(7, 19)), strand=c("+", "-"))
y <- GRanges("chr1", IRanges(5, 10), strand="-")
union(x, y)
union(x, y, ignore.strand=TRUE)
intersect(x, y)
intersect(x, y, ignore.strand=TRUE)
setdiff(x, y)
setdiff(x, y, ignore.strand=TRUE)

## With 2 `GRangesList` objects:
gr1 <- GRanges(seqnames="chr2",
               ranges=IRanges(3, 6))
gr2 <- GRanges(seqnames=c("chr1", "chr1"),
               ranges=IRanges(c(7,13), width = 3),
               strand=c("+", "+", "+", "-"))
gr3 <- GRanges(seqnames=c("chr1", "chr2"),
               ranges=IRanges(c(1, 4), c(3, 9)),
               strand=c("-", "-", "-"))
grlist <- GRangesList(gr1=gr1, gr2=gr2, gr3=gr3)
union(grlist, shift(grlist, 3))
intersect(grlist, shift(grlist, 3))
```
```r
setdiff(grlist, shift(grlist, 3))

## Sanity checks:
grlist2 <- shift(grlist, 3)
stopifnot(identical(
    union(grlist, grlist2),
    mendoapply(union, grlist, grlist2) )
))
stopifnot(identical(
    intersect(grlist, grlist2),
    mendoapply(intersect, grlist, grlist2) )
))
stopifnot(identical(
    setdiff(grlist, grlist2),
    mendoapply(setdiff, grlist, grlist2) )
))

## ---------------------------------------------------------------------
## B. PARALLEL SET OPERATIONS
## ---------------------------------------------------------------------
punion(x, shift(x, 6))
## Not run:
punion(x, shift(x, 7)) # will fail
## End(Not run)
punion(x, shift(x, 7), fill.gap=TRUE)
pintersect(x, shift(x, 6))
pintersect(x, shift(x, 7))
psetdiff(x, shift(x, 7))

## ---------------------------------------------------------------------
## C. MORE EXAMPLES
## ---------------------------------------------------------------------
## GRanges object:
gr <- GRanges(seqnames=c("chr2", "chr1", "chr1"),
ranges=IRanges(1:3, width = 12),
strand=Rle(strand(c("-", "+", "-"))))

## Parallel intersection of a GRanges and a GRangesList object
pintersect(gr, grlist)
pintersect(grlist, gr)

## For a fast 'mendoapply(intersect, grlist, as(gr, "GRangesList"))'
## call pintersect() with 'strict.strand=TRUE' and call reduce() on
## the result with 'drop.empty.ranges=TRUE':
reduce(pintersect(grlist, gr, strict.strand=TRUE),
     drop.empty.ranges=TRUE)

## Parallel set difference of a GRanges and a GRangesList object
psetdiff(gr, grlist)
```
Description

A bunch of useful strand and invertStrand methods.

Usage

```r
## S4 method for signature 'missing'
strand(x)
## S4 method for signature 'character'
strand(x)
## S4 method for signature 'factor'
strand(x)
## S4 method for signature 'integer'
strand(x)
## S4 method for signature 'logical'
strand(x)
## S4 method for signature 'Rle'
strand(x)
## S4 method for signature 'RleList'
strand(x)
## S4 method for signature 'DataTable'
strand(x)
## S4 replacement method for signature 'DataTable,ANY'
strand(x) <- value

## S4 method for signature 'character'
invertStrand(x)
## S4 method for signature 'factor'
invertStrand(x)
## S4 method for signature 'integer'
invertStrand(x)
## S4 method for signature 'logical'
invertStrand(x)
## S4 method for signature 'Rle'
invertStrand(x)
## S4 method for signature 'RleList'
invertStrand(x)
```

Arguments

- **x**: The object from which to obtain a strand factor, strand factor Rle, or strand factor RleList object. Can be missing. See Details and Value sections below for more information.
- **value**: Replacement value for the strand.
Details

All the `strand` and `invertStrand` methods documented here return either a `strand factor`, `strand factor Rle`, or `strand factor RleList` object. These are factor, factor-Rle, or factor-RleList objects containing the "standard strand levels" (i.e. +, -, and *) and no NAs.

Value

All the `strand` and `invertStrand` methods documented here return an object that is parallel to input object `x` when `x` is a character, factor, integer, logical, Rle, or RleList object.

For the `strand` methods:

- If `x` is missing, returns an empty factor with the "standard strand levels" i.e. +, -, and *.
- If `x` is a character vector or factor, it is coerced to a factor with the levels listed above. NA values in `x` are not accepted.
- If `x` is an integer vector, it is coerced to a factor with the levels listed above. 1, -1, and NA values in `x` are mapped to the +, -, and * levels respectively.
- If `x` is a logical vector, it is coerced to a factor with the levels listed above. FALSE, TRUE, and NA values in `x` are mapped to the +, -, and * levels respectively.
- If `x` is a character-, factor-, integer-, or logical-Rle, it is transformed with `runValue(x) <- strand(runValue(x))` and returned.
- If `x` is an RleList object, each list element in `x` is transformed by calling `strand()` on it and the resulting RleList object is returned. More precisely the returned object is `endoapply(x, strand)`.
- If `x` inherits from DataTable, the "strand" column is passed thru `strand()` and returned. If `x` has no "strand" column, this return value is populated with *s.

Each `invertStrand` method returns the same object as its corresponding `strand` method but with + and - switched.

strand(x2)
invertStrand(x2)
strand(x3)
```
tile-methods

Generate windows for a GenomicRanges

description

`tile` and `slidingWindows` methods for GenomicRanges. `tile` partitions each range into a set of tiles, which are defined in terms of their number or width. `slidingWindows` generates sliding windows of a specified width and frequency.

Usage

```r
## S4 method for signature 'GenomicRanges'
tile(x, n, width)

## S4 method for signature 'GenomicRanges'
slidingWindows(x, width, step=1L)
```

Arguments

- `x` A GenomicRanges object, like a GRanges.
- `n` The number of tiles to generate. See `?tile` in the IRanges package for more information about this argument.
width

The (maximum) width of each tile. See ?tile in the \texttt{IRanges} package for more information about this argument.

step

The distance between the start positions of the sliding windows.

Details

The \texttt{tile} function splits \texttt{x} into a \texttt{GRangesList}, each element of which corresponds to a tile, or partition, of \texttt{x}. Specify the tile geometry with either \texttt{n} or \texttt{width} (not both). Passing \texttt{n} creates \texttt{n} tiles of approximately equal width, truncated by sequence end, while passing \texttt{width} tiles the region with ranges of the given width, again truncated by sequence end.

The \texttt{slidingWindows} function generates sliding windows within each range of \texttt{x}, according to \texttt{width} and \texttt{step}, returning a \texttt{GRangesList}. If the sliding windows do not exactly cover a range in \texttt{x}, the last window is partial.

Value

A \texttt{GRangesList} object, each element of which corresponds to a window.

Author(s)

M. Lawrence

See Also

\texttt{tile} in the \texttt{IRanges} package.

Examples

```r
gr <- GRanges(
    seqnames=Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
    ranges=IRanges(1:10, end=11),
    strand=Rle(strand(c("-", "+", "+", "+", "-")), c(1, 2, 2, 3, 2)),
    seqlengths=c(chr1=11, chr2=12, chr3=13))

# split every range in half
tiles <- tile(gr, n = 2L)
stopifnot(all(elementNROWS(tiles) == 2L))

# split ranges into subranges of width 2
# odd width ranges must contain one subrange of width 1
tiles <- tile(gr, width = 2L)
stopifnot(all(all(width(tiles) %in% c(1L, 2L))))

windows <- slidingWindows(gr, width=3L, step=2L)
width(windows[[1L]]) # last range is truncated
```
tileGenome

Put (virtual) tiles on a given genome

Description

tileGenome returns a set of genomic regions that form a partitioning of the specified genome. Each region is called a "tile".

Usage

tileGenome(seqlengths, ntile, tilewidth, cut.last.tile.in.chrom=FALSE)

Arguments

- seqlengths: Either a named numeric vector of chromosome lengths or a Seqinfo object. More precisely, if a named numeric vector, it must have a length \( \geq 1 \), cannot contain NAs or negative values, and cannot have duplicated names. If a Seqinfo object, then it's first replaced with the vector of sequence lengths stored in the object (extracted from the object with the seqlengths getter), then the restrictions described previously apply to this vector.

- ntile: The number of tiles to generate.

- tilewidth: The desired tile width. The effective tile width might be slightly different but is guaranteed to never be more than the desired width.

- cut.last.tile.in.chrom: Whether or not to cut the last tile in each chromosome. This is set to FALSE by default. Can be set to TRUE only when tilewidth is specified. In that case, a tile will never overlap with more than 1 chromosome and a GRanges object is returned with one element (i.e. one genomic range) per tile.

Value

If cut.last.tile.in.chrom is FALSE (the default), a GRangesList object with one list element per tile, each of them containing a number of genomic ranges equal to the number of chromosomes it overlaps with. Note that when the tiles are small (i.e. much smaller than the chromosomes), most of them only overlap with a single chromosome.

If cut.last.tile.in.chrom is TRUE, a GRanges object with one element (i.e. one genomic range) per tile.

Author(s)

H. Pagès, based on a proposal by M. Morgan

- GRangesList and GRanges objects.
- Seqinfo objects and the seqlengths getter.
- IntegerList objects.
- Views objects.
Examples

```r
## A. WITH A TOY GENOME

seqlengths <- c(chr1=60, chr2=20, chr3=25)

## Create 5 tiles:
tiles <- tileGenome(seqlengths, ntile=5)
tiles
elementNROWS(tiles) # tiles 3 and 4 contain 2 ranges

width(tiles)
## Use sum() on this IntegerList object to get the effective tile
## widths:
sum(width(tiles)) # each tile covers exactly 21 genomic positions

## Create 9 tiles:
tiles <- tileGenome(seqlengths, ntile=9)
elementNROWS(tiles) # tiles 6 and 7 contain 2 ranges
table(sum(width(tiles))) # some tiles cover 12 genomic positions,
# others 11

## Specify the tile width:
tiles <- tileGenome(seqlengths, tilewidth=20)
length(tiles) # 6 tiles
table(sum(width(tiles))) # effective tile width is <= specified

## Specify the tile width and cut the last tile in each chromosome:
tiles <- tileGenome(seqlengths, tilewidth=24,
cut.last.tile.in.chrom=TRUE)
tiles
width(tiles) # each tile covers exactly 24 genomic positions, except
# the last tile in each chromosome

## Partition a genome by chromosome ("natural partitioning"):
tiles <- tileGenome(seqlengths, tilewidth=max(seqlengths),
cut.last.tile.in.chrom=TRUE)
tiles # one tile per chromosome

## sanity check
stopifnot(all.equal(setNames(end(tiles), seqnames(tiles)), seqlengths))

## B. WITH A REAL GENOME

library(BSgenome.Scerevisiae.UCSC.sacCer2)
tiles <- tileGenome(seqinfo(Scerevisiae), ntile=20)
tiles
tiles <- tileGenome(seqinfo(Scerevisiae), tilewidth=50000,
cut.last.tile.in.chrom=TRUE)
tiles
```
## C. AN APPLICATION: COMPUTE THE BINNED AVERAGE OF A NUMERICAL VARIABLE DEFINED ALONG A GENOME

See 'genomicvars' for an example of how to compute the binned average of a numerical variable defined along a genome.
