Package ‘LMGene’

December 21, 2016

Version 2.30.0
Date 2013-07-24
Title LMGene Software for Data Transformation and Identification of Differentially Expressed Genes in Gene Expression Arrays
Author David Rocke, Geun Cheol Lee, John Tillinghast, Blythe Durbin-Johnson, and Shiquan Wu
Depends R (>= 2.10.0), Biobase (>= 2.5.5), multtest, survival, affy
Suggests affydata
Maintainer Blythe Durbin-Johnson <bpdurbin@ucdavis.edu>
Description LMGene package for analysis of microarray data using a linear model and glog data transformation
License LGPL
URL http://dmrocke.ucdavis.edu/software.html
biocViews Microarray, DifferentialExpression, Preprocessing
NeedsCompilation no

Description

Computes two sets of p-values per gene or probe via gene-by-gene ANOVA, using both the gene-specific MSE and the posterior MSE for each term in the ANOVA. P-values are not adjusted for multiple testing.
Assumes a fixed effects model and that the correct denominator for all comparisons is the MSE.

Usage

genediff(eS, model = NULL, method = c("MLE", "MOM", "MOMlog"),
          verbose = TRUE)

Arguments

eS An ExpressionSet object. Any transformation and normalization of exprs(eS) should be conducted prior to use in genediff.
model Model used for comparison; see details and LMGene.
method Method by which posterior p-values are calculated. Default "MLE".
verbose If TRUE, the prior degrees of freedom and mean reciprocal precision are printed. See details.

Details

The argument eS must be an ExpressionSet object from the Biobase package. If you have data in a matrix and information about experimental design factors, then you can use neweS to convert the data into an ExpressionSet object. Please see neweS for more detail.

The model argument is an optional character string, constructed like the right-hand side of a formula for lm. It specifies which of the variables in the ExpressionSet will be used in the model and whether interaction terms will be included. If model=NULL, it uses all variables from the ExpressionSet without interactions. Be careful of using interaction terms with factors; this often leads to overfitting, which will yield an error.

The method argument specifies how the adjusted MSE and degrees of freedom should be calculated for use in computation of the posterior p-values:

"MLE" Default. Calculate adjusted MSE and degrees of freedom by maximum likelihood estimation, as described in Wright and Simon (2003).
"MOM" Calculate adjusted MSE and degrees of freedom by method of moments, as described in Rocke (2003).
"MOMlog" Calculate adjusted MSE and degrees of freedom by method of moments on log scale, as described in Smyth (2004). Uses functions fitFdist and trigammainverse from the package limma. Note that the method of Smyth (2004) is used here to calculate the posterior MSE, but not to directly calculate the posterior p-values.
All three methods assume that the gene-specific MSE’s follow a gamma distribution with mean tau. (NB: Notation and parameterization vary somewhat between each of the source papers.) The mean of the gamma distribution, tau, is modeled with an inverse gamma prior with hyperparameters alpha and beta. Empirical Bayes methods are used to estimate the prior hyperparameters, either by maximum likelihood, method of moments, or method of moments on the log scale. The "posterior MSE" is the posterior mean of the variances given the observed gene-specific MSE's.

If verbose = TRUE, the function prints the estimated prior degrees of freedom, which equals twice the prior shape parameter alpha, and the estimated prior mean reciprocal precision, or 1/(alpha*beta).

All p-values are calculated from fixed-effects ANOVA F statistics, using either the gene-specific MSE or the posterior MSE as the denominator.

Value
A list with components:
- Gene.Specific A matrix of p-values calculated using the gene-specific MSE, with one row for each gene/probe and one column for each factor
- Posterior A matrix of p-values calculated using the posterior MSE, with one row for each gene/probe and one column for each factor

pvlist$Posterior[1:5,]
```

glog

*Generalized log transformation function*

### Description

This function transforms the input values by the generalized log function.

### Usage

```
glog(y, lambda)
```

### Arguments

- `y` A data matrix
- `lambda` Transformation parameter

### Details

The glog transformation of a variable y is defined as \( \log(y + \sqrt{y^2 + \lambda}) \). Using \( \lambda = 0 \) corresponds to the log transformation, up to a scale factor of 2. (Other, equivalent expressions exist for the glog transformation. See Durbin et al. (2002) and Huber et al. (2002) for further details.)

The input matrix y may be modified prior to transformation by subtracting a constant or vector ("alpha"). The parameters lambda and alpha may be estimated from `tranest`.

### Value

- `yt` A matrix of glog-transformed values

### Author(s)

David Rocke and Geun-Cheol Lee

### References

http://dmrocke.ucdavis.edu

### See Also

- `tranest`
- `transeS`

**Examples**

```r
#library
library(Biobase)
library(LMGene)

#data
data(sample.mat)
sample.mat[1:5,1:4]

GloggedSmpd<-glog(sample.mat-50,500)
GloggedSmpd[1:5,1:4]
```

---

**LMGene**

---

**LMGene main function**

---

**Description**

LMGene calls function `genediff` to calculate the unadjusted gene-specific and posterior p-values of all genes and then calculates the FDR-adjusted p-values of all genes. Significant genes for each factor in `model` (based on either the gene-specific or posterior FDR-adjusted p-values) are output.

**Usage**

```r
LMGene(eS, model = NULL, level = 0.05, posterior = FALSE, method = c("MLE", "MOM", "MOMlog"))
```

**Arguments**

- `eS` An `ExpressionSet` object. Any transformation and normalization of `exprs(eS)` should be conducted prior to use in `LMGene`.
- `model` Specifies model to be used. Default is to use all variables from `eS` without interactions. See details.
- `level` Significance level
- `posterior` If `TRUE`, the posterior FDR-adjusted p-values are used in listing significant genes for each factor. Default is to use gene-specific FDR-adjusted p-values.
- `method` Method by which the posterior p-values are calculated. Default is "MLE".

**Details**

If you have data in a matrix and information about experimental design factors, then you can use `neweS` to convert the data into an `ExpressionSet` object. Please see `neweS` for more detail.

The `level` argument indicates the False Discovery Rate, e.g. `level=0.05` means a 5 percent FDR.

The `model` argument is an optional character string, constructed like the right-hand side of a formula for `lm`. It specifies which of the variables in the `ExpressionSet` will be used in the model and whether interaction terms will be included. If `model=NULL`, it uses all variables from the `ExpressionSet` without interactions. Be careful of using interaction terms with factors; this often leads to overfitting, which will yield an error.

See `genediff` for details of `method`. 
Value

lmres A list with one component for each factor in model. Each component consists of a character vector with one element per significant gene. If no genes are significant for a given factor, the component for that factor is set to "No significant genes".

# Identify significant genes, using an FDR of 1 percent
LMGene(trans.eS, level = 0.01)

---

lnorm

Lowess normalization function

Description

Lowess normalization function

Usage

lnorm(mat1, span = 0.1)

Arguments

mat1 A data matrix to be normalized
span Lowess smoother span. Larger values give more smoothness.
**lnormeS**

**Details**

mat must be a p by n matrix, where p is the number of genes and n is the number of arrays or samples

**Value**

matnorm1 Normalized matrix

**Author(s)**

David Rocke and Geun-Cheol Lee

**References**

http://dmrocke.ucdavis.edu

**See Also**

lnormeS, norm

**Examples**

```r
library(Biobase)
library(LMGene)

# data
data(sample.mat)
data(vlist)

raw.eS <- neweS(sample.mat, vlist)

# glog transform data
trans.eS <- transeS(raw.eS, lambda = 727, alpha = 56)

# normalize
normed.exprs <- lnorm(exprs(trans.eS))
```

---

**lnormeS**

*Function to apply lowess normalization to an expression set.*

**Description**

Like lnorm, but applies to and returns an ExpressionSet or AffyBatch object instead of a matrix.

**Usage**

lnormeS(eS, span=0.1)

**Arguments**

- **eS**
  - An ExpressionSet or AffyBatch object
- **span**
  - Smoothing parameter for lowess. Larger values correspond to more smoothness.
Value

Returns an ExpressionSet with `exprs(eS)` normalized by `lnorm`.

`lnorm`, `norm`

Examples

```r
library(LMGene)
library(Biobase)

data(sample.eS)

# glog transform expression set
trsample.eS <- transeS(sample.eS, 667, 65)

# normalize expression set
normtrsample.eS <- lnorm(eS) (trsample.eS)
```

---

**neweS**

*Coerce a matrix to class ExpressionSet*

Description

This function converts a data matrix into an ExpressionSet object.

Usage

```r
neweS(mat, vlist, vlabel = as.list(names(vlist)))
```

Arguments

- **mat**: A data matrix to be converted.
- **vlist**: A list, each component of which describes a factor in the experimental design.
- **vlabel**: A list of labels for each component of `vlist`.

Details

Each element of a component of `vlist` corresponds to a column of `mat`. See `vlist` for an example.

Value

- **eset**: An ExpressionSet object.
norm

Examples

library(Biobase)
library(LMGene)

data(sample.mat)
data(vlist)

raw.eS <- newE(sample.mat, vlist)

# glog transform data
trans.eS <- transeS(raw.eS, lambda = 727, alpha = 56)

# normalize
normed.exprs <- norm(exprs(trans.eS))

head(normed.exprs)

plotMeanSD(indata, by.rank = TRUE, line = FALSE, ymax = NULL)

Arguments

Argument    | Description                               | Default
-------------|-------------------------------------------|--------
indata       | An object of class matrix, data.frame,ExpressionSet, or AffyBatch |        
by.rank      | If TRUE, the row standard deviations are plotted against the ranks of the row means. Otherwise, the row standard deviations are plotted against the row means themselves. |        
line         | If TRUE, a lowess smoother line is drawn on the plot. |        
ymax         | The upper limit for the plot y-axis. If missing, axis limits are generated automatically by plot. |        

Details

Generates a scatter plot of the row standard deviations of a matrix of expression data against the row means or ranks of the row means.

Value

NULL
psmeans

Author(s)
Rachel Chen and Blythe Durbin-Johnson

Examples
library(LMGene)
library(Biobase)
data(sample.eS)
# transform data
trans.eS <- transeS(sample.eS, lambda = 727, alpha = 56)

# plot SD against rank of mean
plotMeanSD(trans.eS, line = TRUE)
plotMeanSD(sample.eS, line = TRUE, ymax = 1000)

psmeans Function to take means of probesets.

Description
Converts an ExpressionSet or AffyBatch object with one row of expression data per probeset into an ExpressionSet or AffyBatch object with one row per probe.

Usage
psmeans(eS, ind)

Arguments
eS An ExpressionSet or AffyBatch object
ind A vector used to indicate which probes go into which probesets.

Details
Each entry of ind corresponds to one probe and tells the number of the probeset it belongs to. See tranestAffyProbeLevel and sample.ind for examples.

Value
Returns an ExpressionSet or AffyBatch object with the expression matrix rows corresponding to probesets instead of individual probes. Elements of the returned ExpressionSet or AffyBatch object are means over each probeset.

Author(s)
John Tillinghast

# lowess normalize
ntrs.eS <- lnormeS(trs.eS)

# take means over probesets
genesample.eS <- psmeans(ntrs.eS, sample.ind)
```

---

**pvadjust**

**P-value adjusting function**

**Description**

This function converts the given raw p-values into the FDR adjusted p-values using R package `multtest`.

**Usage**

```r
pvadjust(pvlist)
```

**Arguments**

- `pvlist`: A list containing raw p-values

**Details**

`pvlist` is the output from `genediff` containing p-values from gene-specific MSE’s and posterior MSE’s.

**Value**

- `pvlist2`: A list with the raw p-values and the newly computed FDR adjusted p-values

**Author(s)**

- David Rocke and Geun-Cheol Lee

names(apvlist)
apvlist$Posterior.FDR[1:5,]
Sample array data for `LMGene`

### Value

**resmat**

A matrix of MSEs and degrees of freedom for all model factors and all genes. The first rows of resmat contain MSE’s for each effect in model, ending with the residual MSE. The remaining rows contain degrees of freedom for each effect in the model, ending with the residual d.f. Each column corresponds to a gene.

### Author(s)

David Rocke and Geun-Cheol Lee

### Examples

```r
library(Biobase)
library(LMGene)

# data
data(sample.mat)
data(vlist)

raw.eS <- neweS(sample.mat, vlist)

# glog transform data
trans.eS <- transeS(raw.eS, lambda = 727, alpha = 56)

# Perform gene-by-gene anova
resmat <- rowaov(trans.eS)
resmat[,1:3]
```

### Description

Sample ExpressionSet class data.

### Usage

data(sample.eS)

### Format

Formal class ExpressionSet [package Biobase].
**Details**

Identical with `neweS(sample.mat, vlist)`, up to metadata.

**Examples**

```r
library(Biobase)
library(LMGene)

#data
data(sample.mat)
data(vlist)

Smpdt <- neweS(sample.mat, vlist)

data(sample.eS)
identical(exprs(sample.eS), exprs(Smpdt))
identical(pData(sample.eS), pData(Smpdt))
```

---

**sample.ind**

*Sample probeset index vector*

**Description**

Vector indicating which probeset each probe belongs to.

**Usage**

```r
data(sample.ind)
```

**Format**

A vector of integers, e.g., c(1,1,1,2,2,3,3,3,4,4,...). Length is equal to the number of probes (rows) in `sample.mat`.

**Examples**

```r
data(sample.eS)
data(sample.ind)
trs.eS <- transeS (sample.eS, 667, 65)
ntrs.eS <- lnormeS(trs.eS)
genesample.eS <- psmeans (ntrs.eS, sample.ind)
```
sample.mat

Sample array data for LMGene package

Description

A matrix of array data

Usage

data(sample.mat)

Format

A matrix measuring 613 rows (probes) by 32 columns (samples).

Examples

library(Biobase)
library(LMGene)

#data
data(sample.mat)
data(vlist)

Smpdt<-$neweS(sample.mat,vlist)
data(sample.eS)
identical(exprs(sample.eS), exprs(Smpdt))
identical(pData(sample.eS), pData(Smpdt))

tranest

Glog transformation parameter estimation function

Description

Estimates parameters for the glog transformation, by maximum likelihood or by minimizing the stability score.

Usage

tranest(eS, ngenes = -1, starting = FALSE, lambda = 1000, alpha = 0,
gradtol = 1e-3, lowessnorm = FALSE, method=1, mult=FALSE, model=NULL,
SD = FALSE, rank = TRUE, model.based = TRUE, rep.arrays = NULL)
Arguments

**eS**
- An ExpressionSet object

**ngenes**
- Number of genes to be used in parameter estimation. Default is to use all genes unless there are more than 100,000, in which case a subset of 50,000 genes is selected at random.

**starting**
- If TRUE, user-specified starting values for lambda and alpha are input to the optimization routine

**lambda**
- Starting value for parameter lambda. Ignored unless starting = TRUE

**alpha**
- Starting value for parameter alpha. Ignored unless starting = TRUE

**gradtol**
- A positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm

**lowessnorm**
- If TRUE, lowess normalization (using lnorm) is used in calculating the likelihood.

**method**
- Determines optimization method. Default is 1, which corresponds to a Newton-type method (see nlm and details.)

**mult**
- If TRUE, tranest will use a vector alpha with one (possibly different) entry per sample. Default is to use same alpha for every sample. SD and mult may not both be TRUE.

**model**
- Specifies model to be used. Default is to use all variables from eS without interactions. See details.

**SD**
- If TRUE, transformation parameters are estimated by minimizing the stability score rather than by maximum likelihood. See details.

**rank**
- If TRUE, the stability score is calculated by regressing the replicate standard deviations on the ranks of the gene/row means (rather than on the means themselves). Ignored unless SD = TRUE

**model.based**
- If TRUE, the stability score is calculated using the standard deviations of residuals from the linear model in model. Ignored unless SD = TRUE

**rep.arrays**
- List of sets of replicate arrays. Each element of rep.arrays should be a vector with entries corresponding to arrays (columns) in exprs(eS) conducted under the same experimental conditions, i.e., with identical rows in pData(eS). Ignored unless SD = TRUE and model.based = FALSE

Details

If you have data in a matrix and information about experimental design factors, then you can use neweS to convert the data into an ExpressionSet object. Please see neweS for more detail.

The model argument is an optional character string, constructed like the right-hand side of a formula for lm. It specifies which of the variables in the ExpressionSet will be used in the model and whether interaction terms will be included. If model=NULL, it uses all variables from the ExpressionSet without interactions. Be careful of using interaction terms with factors; this often leads to overfitting, which will yield an error.

The default estimation method is maximum likelihood. The likelihood is derived by assuming that there exist values for lambda and alpha such that the residuals from the linear model in model, fit to glog-transformed data using those values for lambda and alpha, follow a normal distribution. See Durbin and Rocke (2003) for details.

If SD = TRUE, lambda and alpha are estimated by minimizing the stability score rather than by maximum likelihood. The stability score is defined as the absolute value of the slope coefficient from the regression of the replicate/residual standard deviation on the gene/row means, or on the
rank of the gene/row means. If model.based = TRUE, the stability score is calculated using the standard deviation of residuals from the linear model in model. Otherwise, the stability score is calculated using the pooled standard deviation over sets of replicates in rep.arrays. See Wu and Rocke (2009) for details.

Optimization methods in method are as follows:

1 = Newton-type method, using nlm
2 = Nelder-Mead, using optim
3 = BFGS, using optim
4 = Conjugate gradients, using optim
5 = Simulated annealing, using optim (may only be used when mult = TRUE)

Value

A list with components:

lambda Estimate of transformation parameter lambda
alpha Estimate of transformation parameter alpha

Author(s)

David Rocke, Geun-Cheol Lee, John Tillinghast, Blythe Durbin-Johnson, and Shiquan Wu

**tranestAffyProbeLevel**  
*Glog transformation parameter estimation function for probe-level Affymetrix expression data*

**Description**

Estimates parameters for the glog transformation on probe-level Affymetrix expression data, by maximum likelihood or by minimizing the stability score.

**Usage**

```r
tranestAffyProbeLevel(eS, ngenes = 5000, starting = FALSE, lambda = 1000, alpha = 0, gradtol = 0.001, lowessnorm = FALSE, method = 1, mult = FALSE, model = NULL, SD = FALSE, rank = TRUE, model.based = TRUE, rep.arrays = NULL)
```

**Arguments**

- **eS**: An `AffyBatch` object
- **ngenes**: Number of randomly sampled probesets to be used in estimating the transformation parameter
- **starting**: If `TRUE`, user-specified starting values for lambda and alpha are input to the optimization routine
- **lambda**: Starting value for parameter lambda. Ignored unless `starting = TRUE`
- **alpha**: Starting value for parameter alpha. Ignored unless `starting = TRUE`
- **gradtol**: A positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm
- **lowessnorm**: If `TRUE`, lowess normalization (using `lnorm`) is used in calculating the likelihood.
- **method**: Determines optimization method. Default is 1, which corresponds to a Newton-type method (see `nlm` and details.)
- **mult**: If `TRUE`, tranest will use a vector alpha with one (possibly different) entry per sample. Default is to use same alpha for every sample. SD and mult may not both be `TRUE`.
- **model**: Specifies model to be used. Default is to use all variables from eS without interactions. See details.
- **SD**: If `TRUE`, transformation parameters are estimated by minimizing the stability score. See details.
- **rank**: If `TRUE`, the stability score is calculated by regressing the replicate standard deviation on the rank of the probe/row means (rather than on the means themselves). Ignored unless SD = `TRUE`
- **model.based**: If `TRUE`, the stability score is calculated using the standard deviation of residuals from the linear model in model. Ignored unless SD = `TRUE`
- **rep.arrays**: List of sets of replicate arrays. Each element of rep.arrays should be a vector with entries corresponding to arrays (columns) in `exprs(eS)` conducted under the same experimental conditions, i.e., with identical rows in `pData(eS)`. Ignored unless SD = `TRUE` and model.based = `FALSE`
Details

The `model` argument is an optional character string, constructed like the right-hand side of a formula for `lm`. It specifies which of the variables in the `ExpressionSet` will be used in the model and whether interaction terms will be included. If `model=NULL`, it uses all variables from the `ExpressionSet` without interactions. Be careful of using interaction terms with factors; this often leads to overfitting, which will yield an error.

The default estimation method is maximum likelihood. The likelihood is derived by assuming that there exist values for `lambda` and `alpha` such that the residuals from the linear model in `model`, fit to glog-transformed data using those values for `lambda` and `alpha`, follow a normal distribution. See Durbin and Rocke (2003) for details.

If `SD = TRUE`, `lambda` and `alpha` are estimated by minimizing the stability score rather than by maximum likelihood. The stability score is defined as the absolute value of the slope coefficient from the regression of the replicate/residual standard deviation on the probe/row means, or on the rank of the probe/row means. If `model.based = TRUE`, the stability score is calculated using the standard deviation of residuals from the linear model in `model`. Otherwise, the stability score is calculated using the pooled standard deviation over sets of replicates in `rep.arrays`. See Wu and Rocke (2009) for details.

A random sample of probsets (of size `ngene`) is sampled from `featureNames(eS)`. Expression data from all probes in the sampled probsets is used in estimating the transformation parameters.

Optimization methods in `method` are as follows:

1 = Newton-type method, using `nlm`
2 = Nelder-Mead, using `optim`
3 = BFGS, using `optim`
4 = Conjugate gradients, using `optim`
5 = Simulated annealing, using `optim` (may only be used when `mult = TRUE`)

Value

A list with components:

- `lambda` Estimate of transformation parameter `lambda`
- `alpha` Estimate of transformation parameter `alpha`

Lei Zhou, David Rocke, Geun-Cheol Lee, John Tillinghast, Blythe Durbin-Johnson, and Shiquan Wu

References

http://dmrocke.ucdavis.edu
Function to apply the glog transform to an expression set.

For each element in the array of expression data, this function applies the glog transform \( y \rightarrow \text{glog}(y - \alpha, \lambda) \). If \( \alpha \) is a vector, it must have one element for each column in \( \text{exprs}(\text{eS}) \).

Usage

\[
\text{transeS}(\text{eS}, \lambda, \alpha)
\]
Arguments

- **eS**: An ExpressionSet or AffyBatch object
- **lambda**: The parameter lambda to be used in the glog transform.
- **alpha**: The alpha parameter(s) for the glog transform. May be a single number used for all samples, or a vector with one entry per sample.

Details

The glog transformation of a variable y is defined as \( \log(y + \sqrt{y^2 + \text{lambda}}) \). Using \( \text{lambda} = 0 \) corresponds to the log transformation, up to a scale factor of 2. (Other, equivalent expressions exist for the glog transformation. See Durbin et al. (2002) and Huber et al. (2002) for further details.)

\( \text{transeS} \) subtracts a (scalar or vector) parameter \( \text{alpha} \) prior to application of the glog transformation, resulting in the expression \( \log(y - \text{alpha} + \sqrt{(y - \text{alpha})^2 + \text{lambda}}) \).

The parameters \( \text{lambda} \) and \( \text{alpha} \) may be estimated using \( \text{tranest} \).

Value

Returns an ExpressionSet or AffyBatch object with the expression matrix glog-transformed.

data(sample.eS)
trsample.eS <- transeS(sample.eS, 667, 65)
```
Sample experimental/phenotype data for LMGene package

Description

List of experimental factors for the sample matrix array data, ’sample.mat’.

Usage

data(vlist)

Examples

library(Biobase)
library(LMGene)

#data
data(vlist)
