Package ‘OGSA’

March 29, 2017

Version 1.4.0
Date 2015-06-25
Title Outlier Gene Set Analysis
Author Michael F. Ochs <ochsm@tcnj.edu>
Description OGSA provides a global estimate of pathway deregulation in cancer subtypes by integrating the estimates of significance for individual pathway members that have been identified by outlier analysis.
Maintainer Michael F. Ochs <ochsm@tcnj.edu>
Depends R (>= 3.2.0)
Imports gplots(>= 2.8.0), limma(>= 3.18.13), Biobase
LazyData true
License GPL (== 2)
biocViews GeneExpression, Microarray, CopyNumberVariation
NeedsCompilation no

OGSA-package

This package uses outlier statistics and gene set analysis to identify deregulated pathways.

Description

The package applies three versions of outlier statistics across multiple molecular data types to create a single estimate at the gene level for the number of outliers relative to normal controls. These gene estimates are used in gene set analysis to determine deregulated pathways. Visualization of outlier calls provide sample specific information on potential drivers of the gene set statistic.

Details

Package: OGSA
Type: Package
Version: 1.0

References

cnv

Copy number variation data

Description

Matrix of copy number variation data.

Usage

cnv

Format

Matrix of 2000 rows by 69 columns with copy number variation data
Description
Counts outliers by Tibshirani-Hastie method by calling outCount after setting up list or by rank outlier method by calling outRank

Usage

copaInt(dataSet, phenotype, tails, thres = 0.05, method='Tibshirani', corr=FALSE, offsets=NULL)

Arguments

dataset: Set of matrices of molecular data
phenotype: Vector of 1 for case, 0 for control
tails: Vector equal to number of matrices with values left or right for where to find outliers
thres: alpha value
method: Tibshirani, Rank
corr: Whether to correct for normal outliers
offsets: A vector equal to the number of matrices which sets the minimum value relative to normal to call outlier (corrected rank only)

Value
A vector with outlier counts by gene

References

Examples

data(ExampleData)

#Set up phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

tailLRL <- c('left', 'right', 'left')

dataSet <- list(expr, meth, cnv)
tibLRL <- copaInt(dataSet, phenotype, tails=tailLRL)
copaIntE

Description

Counts outliers by Tibshirani-Hastie method by calling outCount after setting up list or by rank outlier method by calling outRank

Usage

copaIntE(expressionSet, tails, thres = 0.05, method='Tibshirani', corr=FALSE, offsets=NULL)

Arguments

expressionSet object containing Set of matrices of molecular data and phenotype data (1 for case, 0 for control)
tails Vector equal to number of matrices with values left or right for where to find outliers
thres alpha value
method Tibshirani, Rank
corr Whether to correct for normal outliers
offsets A vector equal to the number of matrices which sets the minimum value relative to normal to call outlier (corrected rank only)

Value

A vector with outlier counts by gene

References

Examples

data(ExampleData)

library(Biobase)
# building the Annotated Data Frame
phenoData <- AnnotatedDataFrame(
  data.frame(
    type = factor(x = pheno, labels = c("Control", "Case")),
    row.names = colnames(expr)
  )
)
# build environment
inputData <- list2env(list(exprs = expr, meth = meth, cnv = cnv))

# build expressionSet - other information can be added here
expressionSet <- ExpressionSet(inputData, phenoData)

# set up values for expr-meth-cnv in that order
tailLRL <- c('left', 'right', 'left')

tibLRL <- copaIntE(expressionSet, tails=tailLRL)

copaStat

---

description

Calculates outlier statistics by the Tibshirani-Hastie method

usage
copaStat (data, phenotype, tail='right', perms=100, permType='array')

arguments
data: A matrix of nGene by nSample
phenotype: A vector of 0s and 1s of length nSample, where 1 = case, 0 = control
tail: Indicates whether outliers are up (right) or down (left) outliers
perms: The number of permutations
permType: By all on array or by gene, if by gene increase perms significantly and plan on lots of time; in theory array should be fine as genes are rescaled

value

A vector with outlier counts by gene

examples
data(ExampleData)

#Set up phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

#set up values for expr-meth-cnv in that order
tailLRL <- c('left', 'right', 'left')

#setup dataList
dataset <- list(expr, meth, cnv)
data <- dataSet[[1]]
tibL <- copaStat(data, phenotype, tail='right', perms=100, permType='array')

### expr

**Description**
Matrix of expression data

**Usage**
expr

**Format**
Matrix of 2000 rows by 69 columns with expression data

### meth

**Description**
Matrix of methylation data

**Usage**
meth

**Format**
Matrix of 2000 rows by 69 columns with methylation data

### outCallRank

**Description**
Counts outliers by the Ghosh method and generates list objects with all outliers noted

**Usage**
outCallRank (dataSet, phenotype, thres=0.05, tail='right', corr=FALSE, offsets=NULL, names=NULL)
outCallRankE

Arguments

dataSet  
Set of matrices of molecular data
phenotype  
A vector of 0s and 1s of length nSample, where 1 = case, 0 = control
thres  
Alpha value
tail  
A vector equal to the number of matrices with values left or right for where to find outliers
corr  
Whether to correct for normal outliers
offsets  
A vector equal to the number of matrices which sets the minimum value relative to normal to call outlier (corrected rank only)
names  
A vector equal to the number of matrices to name molecular type of data (e.g., CNV)

Value

A list with all specific outlier calls for each molecular type in each case sample

References

Examples

data(ExampleData)

#set up dataSet
dataSet <- list(expr, meth, cnv)

# Set up Phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

# set up values for expr-meth-cnsv in that order
tailLRL <- c('Left', 'Right', 'Left')

outRankLRL <- outCallRank(dataSet, phenotype, names=c('Expr', 'Meth', 'CNV'), tail=tailLRL)

Description

Counts outliers by the Ghosh method and generates list objects with all outliers noted
Usage

outCallRankE (expressionSet, thres= 0.05, tail='right', corr=FALSE, offsets=NULL, names=NULL)

Arguments

expressionSet object containing Set of matrices of molecular data and phenotype data (1 for case, 0 for control)
thres Alpha value
tail A vector equal to the number of matrices with values left or right for where to find outliers
corr Whether to correct for normal outliers
offsets A vector equal to the number of matrices which sets the minimum value relative to normal to call outlier (corrected rank only)
names A vector equal to the number of matrices to name molecular type of data (e.g., CNV)

Value

A list with all specific outlier calls for each molecular type in each case sample

Examples

data(ExampleData)

library(Biobase)
# building the Annotated Data Frame
phenoData <- AnnotatedDataFrame(
  data.frame(
    type = factor(x = pheno, labels = c("Control", "Case")),
    row.names = colnames(expr)
  )
)
# build environment
inputData <- list2env(list(exprs = expr, meth = meth, cnv = cnv))
# build expressionSet - other information can be added here
expressionSet <- ExpressionSet(inputData, phenoData)
# set up values for for the tails in the order that they are exported,
# for example:
tailLRL <- c('left', 'right', 'left')
outRankLRL <- outCallRankE(expressionSet, names=c('Expr', 'Meth', 'CNV'),
                            tail=tailLRL)
Description
Counts outliers by the Tibshirani and Hastie method and generates a list object with all outliers noted.

Usage
`outCallTib(dataSet, phenotype, tail="right", corr=FALSE, names=NULL)`

Arguments
- `dataSet` Set of matrices of molecular data
- `phenotype` A vector of 0s and 1s of length nSample, where 1 = case, 0 = control
- `tail` Vector equal to number of matrices with values 'left' or 'right' for where to find outliers
- `corr` whether to correct for normal outliers ONLY for compatibility, since method does not allow determining specific changes in cases, it will just print message if corr = TRUE
- `names` Vector equal to number of matrices to name molecular type of data (e.g., 'CNV').

Value
A list with all specific outlier calls for each molecular type in each case sample.

References

Examples
```r
data(ExampleData)
data('KEGG_BC_GS')

# Set up dataSet
dataSet <- list(expr, meth, cnv)

# Set up Phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

# set up values for expr-meth-cnv in that order
tailLRL <- c('left', 'right', 'left')

outTibLRL <- outCallTib(dataSet, phenotype, names=c('Expr', 'Meth', 'CNV'), tail=tailLRL)
```
outCallTibE

Description
Counts outliers by the Tibshirani and Hastie method and generates a list object with all outliers noted.

Usage
outCallTibE (expressionSet, tail='right', corr=FALSE, names=NULL)

Arguments
- expressionSet: ExpressionSet object containing sets of data and phenotype information.
- tail: Vector equal to number of matrices with values 'left' or 'right' for where to find outliers.
- corr: Whether to correct for normal outliers ONLY for compatibility, since method does not allow determining specific changes in cases, it will just print message if corr = TRUE.
- names: Vector equal to number of matrices to name molecular type of data (e.g., 'CNV').

Value
A list with all specific outlier calls for each molecular type in each case sample.

Examples
data(ExampleData)
data('KEGG_BC_GS')

library(Biobase)
# building the Annotated Data Frame
phenoData <- AnnotatedDataFrame(
  data.frame(
    type = factor(x = pheno, labels = c("Control", "Case")),
    row.names = colnames(expr)
  )
)
# build environment
inputData <- list2env(list(exprs = expr, meth = meth, cnv = cnv))

# build expressionSet - other information can be added here
expressionSet <- ExpressionSet(inputData, phenoData)
outCount

# set up values for for the tails in the order that they are exported, for example:
tailLRL <- c('left', 'right', 'left')

outTibLRL <- outCallTibE(expressionSet, names=c('Expr', 'Meth', 'CNV'), tail=tailLRL)

Description
Counts outliers by the Tibshirani and Hastie method. Adds the ability to subtract for outliers in the normals using corr = TRUE

Usage
outCount (data, phenotype, tail='right', corr=FALSE)

Arguments
- data: A matrix of nGene by nSample
- phenotype: A vector of 0s and 1s of length nSample, where 1 = case, 0 = control
- tail: Indicates whether outliers are up (right) or down (left) outliers
- corr: Whether to correct for normal outliers

Value
A vector with outlier counts by gene

Examples
data(ExampleData)
# Set up Phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

#set up datalist
dataSet <- list(expr,meth,cnv)

# set up values for expr-meth-cn in that order
tailLRL <- c('left', 'right', 'left')

outTibLRL <- outCallTib(dataSet, phenotype=pheno,
    names=c('Expr', 'Meth', 'CNV'), tail=tailLRL)
Description

Creates PDF color map of where outliers occur coded for molecular type

Usage

outMap(outList, geneList, hmName = 'PatSpecMap.pdf', plotName = 'Outliers', truncGene = FALSE, clust=FALSE)

Arguments

outList List with all outliers generated by outCallRank or outCallTib
geneList Gene set to compare against
hmName Name for PDF output file
plotName Header for plot
truncGene if TRUE, only include genes that have outlier in the plot, default is all genes in gene set
clust If TRUE, clusters data and produces dendrograms

Value

A matrix used for generating heatmap

Examples

data(ExampleData)
data('KEGG_BC_GS')

# Set up Phenotype
phenotype <- pheno
names(phenotype) <- colnames(cnv)

# set up datalist
dataSet <- list(expr,meth,cnv)

# set up values for expr-meth-cnv in that order
tailLRL <- c('left', 'right', 'left')

outTibLRL <- outCallTib(dataSet, phenotype=pheno,
                        names=c('Expr', 'Meth', 'CNV'), tail=tailLRL)

# put in your pathways here
outRank

pdgeB <- pathGS$'BIOCARTA_PDGF_PATHWAY'
outMap(outTibLRL, pdgeB, hmName='BC_PDGF_TIB.pdf', plotName='PDGF
Outlier T-H LRL Calls')

Description
Counts outliers by the Ghosh method.

Usage
outRank (dataSet, phenotype, thres= 0.05, tail='right', corr=FALSE,
offsets=NULL)

Arguments
dataSet Set of matrices of molecular data
phenotype Vector of 1 for case, 0 for control
thres Alpha value
tail Vector equal to number of matrices with values 'left' or 'right' for where to find outliers
corr Whether to correct for normal outliers
offsets Vector equal to number of matrices which sets minimum value relative to normal to call outlier (corrected rank only)

Value
A vector with outlier counts by gene

```

**pathGS**

*Gene set defined by BioCarta pathway*

**Description**

A large list containing gene set from the BioCarta pathway

**Usage**

pathGS

**Format**

List of 403 elements

**Details**

Contained in KEGG_BC_GS data frame

**Source**

**pheno**

**Description**

Vector of phenotype data

**Usage**

pheno

**Format**

A vector of 0s and 1s of length 69, where 1 = tumor, 0 = normal
Description

Performs gene set test on outlier counts

Usage

testGScogps (outlierCts, geneSets)

Arguments

outlierCts Vector with gene names and outlier counts
geneSets List of gene sets

Value

A vector with rank sum gene set statistics
