Package ‘PROMISE’

February 1, 2017

Type       Package
Title      PRojection Onto the Most Interesting Statistical Evidence
Description A general tool to identify genomic features with a specific biologically interesting pattern of associations with multiple endpoint variables as described in Pounds et. al. (2009) Bioinformatics 25: 2013-2019
Version    1.26.0
Date       2014-6-24
Author     Stan Pounds <stanley.pounds@stjude.org>, Xueyuan Cao
           <xueyuan.cao@stjude.org>
Maintainer Stan Pounds <stanley.pounds@stjude.org>, Xueyuan Cao
           <xueyuan.cao@stjude.org>
Depends    R (>= 3.1.0), Biobase, GSEABase
Imports    Biobase, GSEABase, stats
License    GPL (>= 2)
LazyLoad   yes
bioCViews  Microarray, OneChannel, MultipleComparison, GeneExpression
NeedsCompilation no

The PROMISE (PRojection Onto the Most Interesting Statistical Evidence) is performed by calling function PROMISE. The array data and endpoint data are passed through an ExpressionSet; the gene set definition is passed through a GeneSetCollection, and PROMISE definition is passed through a data frame. promise.genestat and avg.abs.genestat are called internally by PROMISE. Two R routines for calculating association statistics with individual endpoint variable(jung.rstat and spearman.rstat) are provided in this version. Users could provide their own R routines written in a similar fashion.

References

Examples

``` R
## load sampExprSet, sampGeneSet, phPatt.
data(sampExprSet)
data(sampGeneSet)
data(phPatt)

## Perform PROMISE procedure without GSEA
test1 <- PROMISE(exprSet=sampExprSet,
```
avg.abs.genestat

Function to Compute Gene Set Statistics

Description
A function to calculate the mean of absolute values of statistics based on a gene set definition

Usage
avg.abs.genestat(gene.res, probes, GS.data)

Arguments
gene.res a data frame. Each row gives test statistics for a genomic variable. Each column corresponds to an endpoint variable.
probes a vector that links the gene.res to GS.data.
GS.data a data frame with first column for probe set identifier and second column for gene set identifier. Each row assigns a probe set to a gene set. Each probe set may be assigned to multiple gene sets or no gene set at all.

Value
Return a matrix of statistics. Each row gives the mean absolute value of test statistics of genes belonging to a gene set. The columns are same as in gene.res.

Note
A function internally called by PROMISE.

PROMISE

Examples

```r
## load sampExprSet sampGeneSet.
data(sampExprSet)
data(sampGeneSet)

## extract expression matrix from sampExprSet
Y <- exprs(sampExprSet)
probes <- rownames(Y)

## convert sampGeneSet to a data frame
GS.data <- NULL
for (i in 1:length(sampGeneSet)){
  tt <- sampGeneSet[i][1]
  this.name <- unlist(geneIds(tt))
  this.set <- setName(tt)
  GS.data <- rbind.data.frame(GS.data,
    cbind.data.frame(featureID=as.character(this.name),
      setID=rep(as.character(this.set),
        length(this.name))))
}

## Calculate the mean of absolute values of statistics
## This is only a demo, probe expression values are used
## in stead of statistics
test <- avg.abs.genestat(Y, probes, GS.data)
```

---

### jung.rstat

*Function to Compute Jung's Statistics*

**Description**

Compute statistic that measures the correlation of many continuous variables with a censored time-to-event variable

**Usage**

```r
jung.rstat(x, time.cens, strat = NULL)
```

**Arguments**

- `x` a data frame with row corresponding to probe set and column corresponding to subjects, the order of columns (subjects) should match the order of rows in `time.cens`.  
- `time.cens`
**time.cens**

A data frame with number of row equal to number of column in \( x \). It contains two columns with first for time and second for censor (1 = event, 0 = censored).

**strat**

A vector of stratum to calculate stratified r-type association statistics, default = NULL.

**Value**

Returns a vector of Jun’s r-type association statistics.

**Note**

The order of subjects in \( x \) (column), `time.cens`, and `strat` should all match. The original statistic proposed by Jung, Owzar, and George can be written as a dot-product. The statistic returned by this routine is expressed in the form of a correlation statistic by dividing the dot product by the square root of the lengths of the two vectors in the numerator.

PROMISE

**Examples**

```r
## load sampExprSet.
data(sampExprSet)

## extract expression matrix from sampExprSet
Y <- exprs(sampExprSet)

## extract end point data from sampExprSet
time.cens <- pData(phenoData(sampExprSet))[,3:4]
strat <- pData(phenoData(sampExprSet))$strat

## compute Jung’s r-type association statistics
jungstat <- jung.rstat(Y, time.cens, strat = strat)
```

---

**PhPatt**

**Phenotype Pattern Definition Set**

**Description**

This hypothetical phenotype pattern definition set `PhPatt` has three columns: stat.coef, stat.func, and endpt.vars. It defines an association pattern for three phenotypes.
Usage

 data(phPatt)

---

**PROMISE**

_PRojection onto the Most Interesting Statistical Evidence_

Description

Perform permutation-based test to identify genes with expression levels having a specific biologically interesting pattern of associations with multiple endpoint variables.

Usage

PROMISE(exprSet, geneSet=NULL, promise.pattern, strat.var=NULL, proj0=FALSE, seed=13, nbperm=FALSE, nperms=10000)

Arguments

- **exprSet**: an ExpressionSet class contains minimum of `exprs` (expression matrix) and `phenodata` (AnnotatedDataFrame of endpoint data). Please refer to `Biobase` for details on how to create such an ExpressionSet.
- **geneSet**: a GeneSetCollection class with minimum of `setName` and `geneIDs` for each GeneSet. Please refer to `GSEABase` for how to create such a GeneSetCollection class. The default is NULL which will perform no gene set enrichment analysis.
- **promise.pattern**: a data frame defining the association pattern of interest. The column names must be `stat.coef`, `stat.func`, and `endpt.vars`. The `stat.coef` column gives the coefficients for combining the statistics of association of genomic variables with individual endpoint variable into the ultimate PROMISE statistic. If proj0=TRUE, the `stat.coeff` is ignored. The `stat.func` column gives the name of the R routine that computes the test statistic of association of the endpoint variables. Two R routines (jung.rstat and spearman.rstat) are provided. Users can provide their own routine accordingly. The `endpt.vars` column gives the name(s) of variable(s) in the endpoint data file needed to compute each term of the PROMISE statistic. A common without a space should be used to separate multiple variables that correspond to the same term in the association pattern definition.
- **strat.var**: the name or numeric value of stratum variable in `exprSet` for stratified analysis. The default is NULL which performs an unstratified analysis.
- **proj0**: indicator of whether projection to 0 is performed. It takes two valid values: TRUE or FALSE. If proj0=TRUE, PROMISE statistics is the sum of squares of individual stats and the stat.coeff in promise.pattern is ignored. The default is FALSE.
- **seed**: initial seed of random number generator. The default is 13.
- **nbperm**: indicator of fast permutation using negative binomial strategy, taking two valid values: FALSE or TRUE. The default is FALSE.
- **max.ntail**: number of success if nbperm = T. Further permutation will not be performed for gene(s) or gene set(s) which max.ntail permuted statistics are greater or equal to the observed statistics. The default is 100
- **nperms**: number of permutations. The default is 10,000.
Value

$generes individual genes’ test statistics and p-values for each individual endpoint and PROMISE analysis. If nbperm=T, the last column contains number of permutations for each gene.

$setres gene set’s test statistics and p-values for each individual endpoint and PROMISE analysis. If nbperm=T, the last column contains number of permutations for gene set. If geneSet is NULL, the value of this component is also NULL.

Examples

## load sampExprSet, sampGeneSet, phPatt.
data(sampExprSet)
data(sampGeneSet)
data(phPatt)

## Perform PROMISE procedure without GSEA
test1 <- PROMISE(exprSet=sampExprSet,
geneSet=NULL,
promise.pattern=phPatt,
strat.var=NULL,
proj0=FALSE,
nbperm=FALSE,
max.ntail=10,
seed=13,
nperms=100)

## Perform PROMISE procedure with GSEA and using fast permuation
test2 <- PROMISE(exprSet=sampExprSet,
geneSet=sampGeneSet,
promise.pattern=phPatt,
strat.var=NULL,
proj0=TRUE,
nbperm=TRUE,
max.ntail=10,
seed=13,
nperms=100)
Function to Calculate PROMISE Statistics

Description

A function to calculate individual gene and PROMISE statistics for a defined pattern of association.

Usage

`promise.genestat(Y, ph.data, ph.pattern, strat = NULL, proj0=FALSE)`

Arguments

- `Y`: A data frame with row corresponding to probe set and column corresponding to subjects, the order of column should match order of row in `ph.data`.
- `ph.data`: A data frame with rows corresponding to subjects and columns corresponding to endpoint variables.
- `ph.pattern`: A data frame with column headers: `stat.coef`, `stat.func`, `endpt.vars`. The `stat.coef` column gives the coefficients for combining the statistics of association of genomic variable with individual endpoint variable into the ultimate PROMISE statistic. If `proj0=TRUE`, the `stat.coef` is ignored. The `stat.func` column gives the name of the R routine that computes the test statistic of association of the endpoint variables. `jung.rstat` and `spearman.rstat` are provided. Users can provide their own routines accordingly. The `endpt.vars` column gives the name(s) of variable(s) in `ph.data` needed to compute each term of the PROMISE statistic. A comma without a space should be used to separate multiple variables that correspond to the same term in the association pattern definition.
- `strat`: A vector of stratum to calculate stratified statistics. The default is `NULL`.
- `proj0`: Indicator of whether projection to 0 is performed. It takes two valid values: `TRUE` or `FALSE`. If `proj0=TRUE`, PROMISE statistics is the sum of squares of individual statistics. The default is `FALSE`.

Value

A matrix of statistics. Each row gives gene’s statistics of each individual endpoint and the PROMISE statistics defined in `ph.pattern`.

Note

A function internally called by PROMISE.

PROMISE

Examples

## load sampExprSet, phPatt.
data(sampExprSet)
data(phPatt)

Y <- exprs(sampExprSet)
ph.data <- pData(phenodata(sampExprSet))

test <- promise.genestat(Y, ph.data, phPatt, strat=ph.data[, 5])
test2 <- promise.genestat(Y, ph.data, phPatt, strat=ph.data[, 5], proj0=TRUE)

promise.pattern  PROMISE pattern

Description

PROMISE pattern is a data frame of association pattern definition, consisting of three columns.

Format

PROMISE pattern: The column names must be stat.coef, stat.func, and endpt.vars.

stat.coef column gives the coefficients for combining the statistics of association of genomic variable with individual endpoint variable into the ultimate PROMISE statistic.

stat.func column gives the name of the R routine that computes the test statistic of association of the endpoint variables. Two R routines (jung.rstat and spearman.rstat) are provided in current release. Users can provide their own routine accordingly.

endpt.vars column gives the name(s) of variable(s) in the endpoint data frame needed to compute each term of the PROMISE statistic. If more than one variables involve in one term, they should be separated by a comma without space.

PROMISE
sampExprSet  An Example Expression Set

Description
This hypothetical expression set sampExprSet belongs to an ExpressionSet class. It contains 100 genomic features (probe_1 to probe_100) for 50 subjects (array_1 to array_50) and phenotype data of drugLevel, residualDisease, obsTime, obsCensor and strat. The expression values can be accessed by exprs(sampExprSet). The phenotype data can be accessed by pData(phenoData(sampExprSet)).

Usage
data(sampExprSet)

sampGeneSet  An Example Gene Set Collection

Description
This hypothetical gene set sampGeneSet belongs to a GeneSetCollection class. It contains 10 gene sets (GeneSet class).

Usage
data(sampGeneSet)

spearman.rstat  Function to Calculate Spearman Correlation Statistics

Description
A function to calculate Spearman rank correlation of each gene in an array data with a continuous variable

Usage
spearman.rstat(Y, x, strat = NULL)

Arguments
Y  a numeric data frame. Each row gives values of one genomic variable.
x  a vector of continuous variable.
strat  a vector of stratum to calculate stratified correlation statistics, default = NULL.

Value
Return a vector of Spearman rank correlation statistics.
spearman.rstat
