Package ‘S4Vectors’

March 29, 2017

**Title**  S4 implementation of vectors and lists

**Description**  The S4Vectors package defines the Vector and List virtual classes and a set of generic functions that extend the semantic of ordinary vectors and lists in R. Package developers can easily implement vector-like or list-like objects as concrete subclasses of Vector or List. In addition, a few low-level concrete subclasses of general interest (e.g. DataFrame, Rle, and Hits) are implemented in the S4Vectors package itself (many more are implemented in the IRanges package and in other Bioconductor infrastructure packages).

**Version**  0.12.2

**Encoding**  UTF-8

**Author**  H. Pagès, M. Lawrence and P. Aboyoun

**Maintainer**  Bioconductor Package Maintainer <maintainer@bioconductor.org>

**biocViews**  Infrastructure, DataRepresentation

**Depends**  R (>= 3.3.0), methods, utils, stats, stats4, BiocGenerics (>= 0.15.10)

**Suggests**  IRanges, GenomicRanges, Matrix, ShortRead, graph, data.table, RUnit

**License**  Artistic-2.0

**NeedsCompilation**  yes

**R topics documented:**

- aggregate-methods ....... 2
- Annotated-class .......... 4
- DataFrame-class .......... 5
aggregate-methods

Compute summary statistics of subsets of vector-like objects

Description

The S4Vectors package defines aggregate methods for Vector, Rle, and List objects.

Usage

```r
## S4 method for signature 'Vector'
aggregate(x, by, FUN, start=NULL, end=NULL, width=NULL,
          frequency=NULL, delta=NULL, ..., simplify=TRUE)

## S4 method for signature 'Rle'
aggregate(x, by, FUN, start=NULL, end=NULL, width=NULL,
          frequency=NULL, delta=NULL, ..., simplify=TRUE)

## S4 method for signature 'List'
aggregate(x, by, FUN, start=NULL, end=NULL, width=NULL,
          frequency=NULL, delta=NULL, ..., simplify=TRUE)
```
Arguments

- **x**: A Vector, Rle, or List object.
- **by**: An object with `start`, `end`, and `width` methods.
  - If `x` is a List object, the by parameter can be a RangesList object to aggregate within the list elements rather than across them. When by is a RangesList object, the output is either a SimpleAtomicList object, if possible, or a SimpleList object, if not.
- **FUN**: The function, found via `match.fun`, to be applied to each subset of `x`.
- **start`, `end`, `width**: The start, end, and width of the subsets. If by is missing, then two of the three must be supplied and have the same length.
- **frequency`, `delta**: Optional arguments that specify the sampling frequency and increment within the subsets (in the same fashion as `window` from the stats package does).
- **...**: Optional arguments to `FUN`.
- **simplify**: A logical value specifying whether the result should be simplified to a vector or matrix if possible.

Details

Subsets of `x` can be specified either via the by argument or via the start, end, width, frequency, and delta arguments.

For example, if start and end are specified, then:

```r
aggregate(x, FUN=FUN, start=start, end=end, ..., simplify=simplify)
```

is equivalent to:

```r
sapply(seq_along(start),
  function(i) FUN(x[start[i]:end[i]], ...), simplify=simplify)
```

(replace `x[start[i]:end[i]]` with 2D-style subsetting `x[start[i]:end[i], ]` if `x` is a DataFrame object).

See Also

- The `aggregate` function in the stats package.
- Vector, Rle, List, and DataFrame objects.
- The `start`, `end`, and `width` generic functions defined in the BiocGenerics package.

Examples

```r
x <- Rle(10:2, 1:9)
aggregate(x, x > 4, mean)
aggregate(x, FUN=mean, start=1:26, width=20)
```

## Note that aggregate() works on a DataFrame object the same way it
## works on an ordinary data frame:
```r
aggregate(DataFrame(state.x77), list(Region=state.region), mean)
aggregate(weight ~ feed, data=DataFrame(chickwts), mean)
```
library(IRanges)
by <- IRanges(start=1:26, width=20, names=LETTERS)
aggregate(x, by, is.unsorted)

Annotated-class  Annotated class

Description

The virtual class Annotated is used to standardize the storage of metadata with a subclass.

Details

The Annotated class supports the storage of global metadata in a subclass. This is done through the metadata slot that stores a list object.

Accessors

In the following code snippets, x is an Annotated object.

metadata(x), metadata(x) <- value: Get or set the list holding arbitrary R objects as annotations. May be, and often is, empty.

Author(s)

P. Aboyoun

library(IRanges)
showClass("Annotated")
DataFrame-class

DataFrame objects

Description

The DataFrame class extends the DataTable virtual class and supports the storage of any type of object (with length and [ methods) as columns.

Details

On the whole, the DataFrame behaves very similarly to data.frame, in terms of construction, subsetting, splitting, combining, etc. The most notable exception is that the row names are optional. This means calling rownames(x) will return NULL if there are no row names. Of course, it could return seq_len(nrow(x)), but returning NULL informs, for example, combination functions that no row names are desired (they are often a luxury when dealing with large data).

As DataFrame derives from Vector, it is possible to set an annotation string. Also, another DataFrame can hold metadata on the columns.

For a class to be supported as a column, it must have length and [ methods, where [ supports subsetting only by i and respects drop=FALSE. Optionally, a method may be defined for the showAsCell generic, which should return a vector of the same length as the subset of the column passed to it. This vector is then placed into a data.frame and converted to text with format. Thus, each element of the vector should be some simple, usually character, representation of the corresponding element in the column.

Constructor

DataFrame(..., row.names = NULL, check.names = TRUE): Constructs a DataFrame in similar fashion to data.frame. Each argument in ... is coerced to a DataFrame and combined column-wise. No special effort is expended to automatically determine the row names from the arguments. The row names should be given in row.names; otherwise, there are no row names. This is by design, as row names are normally undesirable when data is large. If check.names is TRUE, the column names will be checked for syntactic validity and made unique, if necessary.

To store an object of a class that does not support coercion to DataFrame, wrap it in I(). The class must still have methods for length and [.

Accessors

In the following code snippets, x is a DataFrame.

dim(x): Get the length two integer vector indicating in the first and second element the number of rows and columns, respectively.

dimnames(x), dimnames(x) <- value: Get and set the two element list containing the row names (character vector of length nrow(x) or NULL) and the column names (character vector of length ncol(x)).

Coercion

as(from, "DataFrame"): By default, constructs a new DataFrame with from as its only column. If from is a matrix or data.frame, all of its columns become columns in the new DataFrame. If from is a list, each element becomes a column, recycling as necessary. Note that for the
DataFrame to behave correctly, each column object must support element-wise subsetting via the \[\text{method} and return the number of elements with length. It is recommended to use the DataFrame constructor, rather than this interface.

\text{as.list}(x): Coerces x, a DataFrame, to a list.
\text{as.data.frame}(x, row.names=NULL, optional=FALSE): Coerces x, a DataFrame, to a data.frame. Each column is coerced to a data.frame and then column bound together. If row.names is NULL, they are retrieved from x, if it has any. Otherwise, they are inferred by the data.frame constructor.

\text{NOTE: conversion of x to a data.frame is not supported if x contains any list, SimpleList, or CompressedList columns.}
\text{as(from, ”data.frame”): Coerces a DataFrame to a data.frame by calling as.data.frame(from).}
\text{as.matrix}(x): Coerces the DataFrame to a matrix, if possible.

\textbf{Subsetting}

In the following code snippets, x is a DataFrame.

\text{x[i,j,drop]: Behaves very similarly to the [.data.frame method, except i can be a logical Rle object and subsetting by matrix indices is not supported. Indices containing NA’s are also not supported.}
\text{x[i,j] <- value: Behaves very similarly to the [<-.data.frame method.}
\text{x[[i]]: Behaves very similarly to the [[.data.frame method, except arguments j and exact are not supported. Column name matching is always exact. Subsetting by matrices is not supported.}
\text{x[[i]] <- value: Behaves very similarly to the [[<-.data.frame method, except argument j is not supported.}

\textbf{Combining}

In the following code snippets, x is a DataFrame.

\text{rbind(...): Creates a new DataFrame by combining the rows of the DataFrame objects in ... Very similar to rbind.data.frame, except in the handling of row names. If all elements have row names, they are concatenated and made unique. Otherwise, the result does not have row names. Currently, factors are not handled well (their levels are dropped). This is not a high priority until there is an XFactor class.}
\text{cbind(...): Creates a new DataFrame by combining the columns of the DataFrame objects in ... Very similar to cbind.data.frame, except row names, if any, are dropped. Consider the DataFrame as an alternative that allows one to specify row names.}

Examples

```r
score <- c(1L, 3L, NA)
counts <- c(10L, 2L, NA)
row.names <- c("one", "two", "three")

df <- DataFrame(score) # single column
df["score"]
df <- DataFrame(score, row.names = row.names) # with row names
rownames(df)

df <- DataFrame(vals = score) # explicit naming
df["vals"]

# arrays
ary <- array(1:4, c(2,1,2))
sw <- DataFrame(I(ary))

# a data.frame
sw <- DataFrame(swiss)
as.data.frame(sw) # swiss, without row names
# now with row names
sw <- DataFrame(swiss, row.names = rownames(swiss))
as.data.frame(sw) # swiss

# subsetting
sw[] # identity subset
sw[,] # same

sw[NULL] # no columns
sw[,NULL] # no columns
sw[NULL,] # no rows

## select columns
sw[1:3]
sw[,] # same as above
sw[, "Fertility"]
sw[, c(TRUE, FALSE, FALSE, FALSE, FALSE, FALSE)]

## select rows and columns
sw[4:5, 1:3]
sw[1] # one-column DataFrame
## the same
sw[, 1, drop = FALSE]
sw[, 1] # a (unnamed) vector
sw[[1]] # the same
sw[["Fertility"]]
sw[["Fert"]]] # should return 'NULL'

sw[1,] # a one-row DataFrame
sw[1,, drop=TRUE] # a list

## duplicate row, unique row names are created
sw[c(1, 1:2),]
```
## indexing by row names
sw["Courtelary",]
subsw <- sw[1:5,1:4]
subsw["C",] # partially matches

## row and column names
cn <- paste("X", seq_len(ncol(swiss)), sep = ".")
colnames(sw) <- cn
colnames(sw)
rn <- seq(nrow(sw))
rownames(sw) <- rn
rownames(sw)

## column replacement
df["counts"] <- counts
df["counts"]
df[[3]] <- score
df["X"]
df[[3]] <- NULL # deletion

DataTable-class  

### Description

DataTable is an API only (i.e. virtual class with no slots) for accessing objects with a rectangular shape like DataFrame or RangedData objects. It mimics the API for standard data.frame objects.

### Accessors

In the following code snippets, x is a DataTable.

- nrow(x), ncol(x): Get the number of rows and columns, respectively.
- NROW(x), NCOL(x): Same as nrow(x) and ncol(x), respectively.
- dim(x): Length two integer vector defined as c(nrow(x), ncol(x)).
- rownames(x), colnames(x): Get the names of the rows and columns, respectively.
- dimnames(x): Length two list of character vectors defined as list(rownames(x), colnames(x)).

### Subsetting

In the code snippets below, x is a DataTable object.

- x[i, j, drop=TRUE]: Return a new DataTable object made of the selected rows and columns. For single column selection, the drop argument specifies whether or not to coerce the returned sequence to a standard vector.
- head(x, n=6L): If n is non-negative, returns the first n rows of the DataTable object. If n is negative, returns all but the last abs(n) rows of the DataTable object.
- tail(x, n=6L): If n is non-negative, returns the last n rows of the DataTable object. If n is negative, returns all but the first abs(n) rows of the DataTable object.
subset(x, subset, select, drop=FALSE): Return a new DataTable object using:

- **subset** logical expression indicating rows to keep, where missing values are taken as FALSE.
- **select** expression indicating columns to keep.
- **drop** passed on to [ indexing operator.

na.omit(object): Returns a subset with incomplete cases removed.

na.exclude(object): Returns a subset with incomplete cases removed (but to be included with NAs in statistical results).

is.na(x): Returns a logical matrix indicating which cells are missing.

complete.cases(x): Returns a logical vector identifying which cases have no missing values.

**Combining**

In the code snippets below, x is a DataTable object.

cbind(...): Creates a new DataTable by combining the columns of the DataTable objects in ...

rbind(...): Creates a new DataTable by combining the rows of the DataTable objects in ...

merge(x, y, ...): Merges two DataTable objects x and y, with arguments in ... being the same as those allowed by the base `merge`. It is allowed for either x or y to be a data.frame.

**Looping**

In the code snippets below, x is a DataTable object.

by(data, INDICES, FUN, ..., simplify = TRUE): Apply FUN to each group of data, a DataTable, formed by the factor (or list of factors) INDICES. Exactly the same contract as `as.data.frame`.

**Utilities**

duplicated(x): Returns a logical vector indicating the rows that are identical to a previous row.

unique(x): Returns a new DataTable after removing the duplicated rows from x.

show(x): By default the show method displays 5 head and 5 tail lines. The number of lines can be altered by setting the global options `showHeadLines` and `showTailLines`. If the object length is less than the sum of the options, the full object is displayed. These options affect GRanges, GAlignments, Ranges, DataTable and XString objects.

**Coercion**

as.env(x, enclos = parent.frame()): Creates an environment from x with a symbol for each colnames(x). The values are not actually copied into the environment. Rather, they are dynamically bound using `makeActiveBinding`. This prevents unnecessary copying of the data from the external vectors into R vectors. The values are cached, so that the data is not copied every time the symbol is accessed.

**Statistical modeling with DataTable**

A number of wrappers are implemented for performing statistical procedures, such as model fitting, with DataTable objects.

**Tabulation:**

xtabs(formula = ~., data, subset, na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)

Like the original `xtabs`, except data is a DataTable.

Examples

showClass("DataTable") # shows (some of) the known subclasses

library(IRanges)
df <- DataFrame(as.data.frame(UCBAdmissions))
xtabs(Freq ~ Gender + Admit, df)

expand

Unlist the list-like columns of a DataFrame object

Description

expand transforms a DataFrame object into a new DataFrame object where the columns specified by the user are unlisted. The transformed DataFrame object has the same colnames as the original but typically more rows.

Usage

## S4 method for signature 'DataFrame'
expand(x, colnames, keepEmptyRows = FALSE)

Arguments

x
A DataFrame object with list-like columns or a Vector object with list-like metadata columns (i.e. with list-like columns in mcols(x)).

colnames
A character or numeric vector containing the names or indices of the list-like columns to unlist. The order in which columns are unlisted is controlled by the column order in this vector. This defaults to all of the recursive (list-like) columns in x.

keepEmptyRows
A logical indicating if rows containing empty list elements in the specified colnames should be retained or dropped. When TRUE, list elements are replaced with NA and all rows are kept. When FALSE, rows with empty list elements in the colnames columns are dropped.

Value

A DataFrame object that has been expanded row-wise to match the length of the unlisted columns.

See Also

- DataFrame objects.
Examples

```r
library(IRanges)
aa <- CharacterList("a", paste0("d", 1:2), paste0("b", 1:3), c(), "c")
bb <- CharacterList(paste0("sna", 1:2), "foo", paste0("bar", 1:3), c(), "hica")
df <- DataFrame(aa=aa, bb=bb, cc=11:15)

## Expand by all list-like columns (aa, bb), dropping rows with empty
## list elements:
expand(df)

## Expand the aa column only:
expand(df, colnames="aa", keepEmptyRows=TRUE)
expand(df, colnames="aa", keepEmptyRows=FALSE)

## Expand the aa and then the bb column:
expand(df, colnames=c("aa","bb"), keepEmptyRows=TRUE)
expand(df, colnames=c("aa","bb"), keepEmptyRows=FALSE)
```

---

**FilterMatrix-class**  
*Matrix for Filter Results*

**Description**

A FilterMatrix object is a matrix meant for storing the logical output of a set of FilterRules, where each rule corresponds to a column. The FilterRules are stored within the FilterMatrix object, for the sake of provenance. In general, a FilterMatrix behaves like an ordinary matrix.

**Accessor methods**

In the code snippets below, x is a FilterMatrix object.

filterRules(x): Get the FilterRules corresponding to the columns of the matrix.

**Constructor**

FilterMatrix(matrix, filterRules): Constructs a FilterMatrix, from a given matrix and filterRules. Not usually called by the user, see `evalSeparately`.

**Utilities**

summary(object, discarded = FALSE, percent = FALSE): Returns a numeric vector containing the total number of records (nrow), the number passed by each filter, and the number of records that passed every filter. If discarded is TRUE, then the numbers are inverted (i.e., the values are subtracted from the number of rows). If percent is TRUE, then the numbers are percent of total.

**Author(s)**

Michael Lawrence

**See Also**

- `evalSeparately` is the typical way to generate this object.
- `FilterRules` objects.
FilterRules-class

Collection of Filter Rules

Description

A FilterRules object is a collection of filter rules, which can be either expression or function objects. Rules can be disabled/enabled individually, facilitating experimenting with different combinations of filters.

Details

It is common to split a dataset into subsets during data analysis. When data is large, however, representing subsets (e.g. by logical vectors) and storing them as copies might become too costly in terms of space. The FilterRules class represents subsets as lightweight expression and/or function objects. Subsets can then be calculated when needed (on the fly). This avoids copying and storing a large number of subsets. Although it might take longer to frequently recalculate a subset, it often is a relatively fast operation and the space savings tend to be more than worth it when data is large.

Rules may be either expressions or functions. Evaluating an expression or invoking a function should result in a logical vector. Expressions are often more convenient, but functions (i.e. closures) are generally safer and more powerful, because the user can specify the enclosing environment. If a rule is an expression, it is evaluated inside the envir argument to the eval method (see below). If a function, it is invoked with envir as its only argument. See examples.

Accessor methods

In the code snippets below, x is a FilterRules object.

active(x): Get the logical vector of length length(x), where TRUE for an element indicates that the corresponding rule in x is active (and inactive otherwise). Note that names(active(x)) is equal to names(x).

active(x) <- value: Replace the active state of the filter rules. If value is a logical vector, it should be of length length(x) and indicate which rules are active. Otherwise, it can be either numeric or character vector, in which case it sets the indicated rules (after dropping NA's) to active and all others to inactive. See examples.

Constructor

FilterRules(exprs = list(), ..., active = TRUE): Constructs a FilterRules with the rules given in the list exprs or in .... The initial active state of the rules is given by active, which is recycled as necessary. Elements in exprs may be either character (parsed into an expression), a language object (coerced to an expression), an expression, or a function that takes at least one argument. IMPORTANTLY, all arguments in ... are quote()’d and then coerced to an expression. So, for example, character data is only parsed if it is a literal. The names of the filters are taken from the names of exprs and .... if given. Otherwise, the character vectors take themselves as their name and the others are deparsed (before any coercion). Thus, it is recommended to always specify meaningful names. In any case, the names are made valid and unique.
Subsetting and Replacement

In the code snippets below, \( x \) is a \texttt{FilterRules} object.

- \( x[i] \): Subsets the filter rules using the same interface as for \texttt{Vector}.
- \( x[[i]] \): Extracts an expression or function via the same interface as for \texttt{List}.
- \( x[[i]] <- \) value: The same interface as for \texttt{List}. The default active state for new rules is \texttt{TRUE}.

Combining

In the code snippets below, \( x \) is a \texttt{FilterRules} object.

- \texttt{append(x, values, after = length(x))}: Appends the values \texttt{FilterRules} instance onto \( x \) at the index given by \texttt{after}.
- \texttt{c(x, ..., recursive = FALSE)}: Concatenates the \texttt{FilterRule} instances in \( ... \) onto the end of \( x \).

Evaluating

\[
eval(expr, envir = \text{parent.frame}(), \quad \text{enclos} = \text{if (is.list(envir) || is.pairlist(envir)) parent.frame}() \quad \text{else baseenv}()) \quad \text{evaluates a FilterRules instance (passed as the expr argument). Expression rules are evaluated in envir, while function rules are invoked with envir as their only argument. The evaluation of a rule should yield a logical vector. The results from the rule evaluations are combined via the AND operation (i.e. \&) so that a single logical vector is returned from eval.}
\]

\[
evalSeparately(expr, envir = \text{parent.frame}(), \quad \text{enclos} = \text{if (is.list(envir) || is.pairlist(envir)) parent.frame}() \quad \text{else baseenv}()) \quad \text{evaluates separately each rule in a FilterRules instance (passed as the expr argument). Expression rules are evaluated in envir, while function rules are invoked with envir as their only argument. The evaluation of a rule should yield a logical vector. The results from the rule evaluations are combined into a logical matrix, with a column for each rule. This is essentially the parallel evaluator, while \text{eval} is the serial evaluator.}
\]

\[
esubsetByFilter(x, filter) \quad \text{evaluates filter on x and uses the result to subset x. The result contains only the elements in x for which filter evaluates to \texttt{TRUE}.}
\]

\[
s\text{ummary(object, subject): Returns an integer vector with the number of elements in subject that pass each rule in object, along with a count of the elements that pass all filters.}
\]

Filter Closures

When a closure (function) is included as a filter in a \texttt{FilterRules} object, it is converted to a \texttt{FilterClosure}, which is currently nothing more than a marker class that extends \texttt{function}. When a \texttt{FilterClosure} filter is extracted, there are some accessors and utilities for manipulating it:

- \texttt{params}: Gets a named list of the objects that are present in the enclosing environment (without inheritance). This assumes that a filter is constructed via a constructor function, and the objects in the frame of the constructor (typically, the formal arguments) are the parameters of the filter.

Author(s)

Michael Lawrence

See Also

\texttt{FilterMatrix} objects for storing the logical output of a set of \texttt{FilterRules} objects.
Examples

```r
## constructing a FilterRules instance

## an empty set of filters
filters <- FilterRules()

## as a simple character vector
filt <- c("peaks", "promoters")
filters <- FilterRules(filt)
active(filters) # all TRUE

## with functions and expressions
filt <- list(peaks = expression(peaks), promoters = expression(promoters),
             find_eboxes = function(rd) rep(FALSE, nrow(rd)))
filters <- FilterRules(filt, active = FALSE)
active(filters) # all FALSE

## direct, quoted args (character literal parsed)
filters <- FilterRules(under_peaks = peaks, in_promoters = "promoters")

## specify both exprs and additional args
filters <- FilterRules(filt, diffexp = de)

## evaluation
df <- DataFrame(peaks = c(TRUE, TRUE, FALSE, FALSE),
                 promoters = c(TRUE, FALSE, FALSE, TRUE),
                 introns = c(TRUE, FALSE, FALSE, FALSE))
eval(filters, df)
fm <- evalSeparately(filters, df)
identical(filterRules(fm), filters)
summary(fm)
summary(fm, percent = TRUE)
fm <- evalSeparately(filters, df, serial = TRUE)

## set the active state directly
active(filters) <- FALSE # all FALSE
active(filters) <- TRUE # all TRUE
active(filters) <- c(FALSE, FALSE, TRUE) # use a filter name

## toggle the active state by name or index
active(filters) <- c(NA, 2) # NA's are dropped
active(filters) <- c("peaks", NA)
```

---

**Hits-class**

**Hits objects**
**Hits-class**

**Description**

The Hits class is a container for representing a set of hits between a set of left nodes and a set of right nodes. Note that only the hits are stored in the object. No information about the left or right nodes is stored, except their number.

For example, the findOverlaps function, defined and documented in the IRanges package, returns the hits between the query and subject arguments in a Hits object.

**Usage**

```r
## Constructor functions

Hits(from=integer(0), to=integer(0), nLnode=0L, nRnode=0L, ..., sort.by.query=FALSE)

SelfHits(from=integer(0), to=integer(0), nnode=0L, ..., sort.by.query=FALSE)
```

**Arguments**

- `from`, `to` 2 integer vectors of the same length. The values in from must be >= 1 and <= nLnode. The values in to must be >= 1 and <= nRnode.
- `nLnode`, `nRnode` Number of left and right nodes.
- `...` Metadata columns to set on the Hits object. All the metadata columns must be vector-like objects of the same length as from and to.
- `sort.by.query` Should the hits in the returned object be sorted by query? If yes, then a SortedByQueryHits object is returned (SortedByQueryHits is a subclass of Hits).
- `nnode` Number of nodes.

**Accessors**

In the code snippets below, `x` is a Hits object.

- `length(x)`: get the number of hits
- `from(x)`: Equivalent to `as.data.frame(x)[[1]]`
- `to(x)`: Equivalent to `as.data.frame(x)[[2]]`
- `nLnode(x), nrow(x)`: get the number of left nodes
- `nRnode(x), ncol(x)`: get the number of right nodes
- `countLnodeHits(x)`: Counts the number of hits for each left node, returning an integer vector.
- `countRnodeHits(x)`: Counts the number of hits for each right node, returning an integer vector.

The following accessors are just aliases for the above accessors:

- `queryHits(x)`: alias for `from(x)`.
- `subjectHits(x)`: alias for `to(x)`.
- `queryLength(x)`: alias for `nLnode(x)`.
- `subjectLength(x)`: alias for `nRnode(x)`.
- `countQueryHits(x)`: alias for `countLnodeHits(x)`.
- `countSubjectHits(x)`: alias for `countRnodeHits(x)`.
**Coercion**

In the code snippets below, x is a Hits object.

- `as.matrix(x)`: Coerces x to a two column integer matrix, with each row representing a hit between a left node (first column) and a right node (second column).
- `as.table(x)`: Counts the number of hits for each left node in x and outputs the counts as a table.

**Subsetting**

In the code snippets below, x is a Hits object.

- `x[i]`: Subset the Hits object.

**Other transformations**

In the code snippets below, x is a Hits object.

- `t(x)`: Transpose x by interchanging the left and right nodes. This allows, for example, counting the number of hits for each right node using `as.table`.
- `remapHits(x, Lnodes.remapping=NULL, new.nLnode=NA, Rnodes.remapping=NULL, new.nRnode=NA)`: Only supports SortedByQueryHits objects at the moment. Remaps the left and/or right nodes in x. The left nodes are remapped thru the map specified via the `Lnodes.remapping` and `new.nLnode` arguments. The right nodes are remapped thru the map specified via the `Rnodes.remapping` and `new.nRnode` arguments. `Lnodes.remapping` must represent a function defined on the 1..M interval that takes values in the 1..N interval, where N is `nLnode(x)` and M is the value specified by the user via the `new.nLnode` argument. Note that this mapping function doesn’t need to be injective or surjective. Also it is not represented by an R function but by an integer vector of length M with no NAs. More precisely `Lnodes.remapping` can be NULL (identity map), or a vector of `nLnode(x)` non-NA integers that are >= 1 and <= `new.nLnode`, or a factor of length `nLnode(x)` with no NAs (a factor is treated as an integer vector, and, if missing, `new.nLnode` is taken to be its number of levels). Note that a factor will typically be used to represent a mapping function that is not injective. The same applies to the `Rnodes.remapping`.

`remapHits` returns a Hits object where `from(x)` and `to(x)` have been remapped thru the 2 specified maps. This remapping is actually only the 1st step of the transformation, and is followed by 2 additional steps: (2) the removal of duplicated hits, and (3) the reordering of the hits (first by query hits, then by subject hits). Note that if the 2 maps are injective then the remapping won’t introduce duplicated hits, so, in that case, step (2) is a no-op (but is still performed). Also if the “query map” is strictly ascending and the “subject map” ascending then the remapping will preserve the order of the hits, so, in that case, step (3) is also a no-op (but is still performed).

- `breakTies(x, method=c("first", "last"))`: Restrict the hits so that every left node maps to at most one right node. If method is “first”, for each left node, select the edge with the first (lowest rank) right node, if any. If method is “last”, select the edge with the last (highest rank) right node.

**SelfHits**

A SelfHits object is a Hits object where the left and right nodes are identical. For a SelfHits object x, nLnode(x) is equal to nRnode(x). The object can be seen as an oriented graph where nLnode
is the nb of nodes and the hits are the (oriented) edges. SelfHits objects support the same set of 
accessors as Hits objects plus the nnode() accessor that is equivalent to nLnode() and nRnode().

We also provide two little utilities to operate on a SelfHits object x:

isSelfHit(x): A self hit is an edge from a node to itself. isSelfHit(x) returns a logical vector 
parallel to x indicating which elements in x are self hits.

isRedundantHit(x): When there is more than 1 edge between 2 given nodes (regardless of or-
ientation), the extra edges are considered to be redundant hits. isRedundantHit(x) returns a 
logical vector parallel to x indicating which elements in x are redundant hits.

## See ?'Hits-examples' in the IRanges package for more examples of basic
## manipulation of Hits objects.

## SelfHits objects

```r
hits2 <- SelfHits(c(2, 3, 3, 3, 3, 3, 4, 4, 4), c(4, 3, 2:4, 2, 2:3, 2), 4)
## Hits 2 and 4 are self hits (from 3rd node to itself):
which(isSelfHit(hits2))
## Hits 4, 6, 7, 8, and 9, are redundant hits:
which(isRedundantHit(hits2))

hits3 <- findMatches(x)
hits3[!isSelfHit(hits3)]
hits3[!(isSelfHit(hits3) | isRedundantHit(hits3))]
```

---

### Hits-comparison

#### Comparing and ordering hits

**Description**

`==`, `!=`, `<=`, `>=`, `<`, `>`, `match()`, `%in%`, `order()`, `sort()`, and `rank()` can be used on `Hits` objects to compare and order hits.

Note that only the `pcompare`, `match`, and `order` methods are actually defined for `Hits` objects. This is all what is needed to make all the other comparing and ordering operations (i.e. `==`, `!=`, `<=`, `>=`, `<`, `>`, `%in%`, `sort()`, and `rank()`) work on these objects (see `?Vector-comparison` for more information about this).

#### Usage

```r
## S4 method for signature 'Hits,Hits'
pcompare(x, y)

## S4 method for signature 'Hits,Hits'
match(x, table, nomatch=NA_integer_, incomparables=NULL, method=c("auto", "quick", "hash"))

## S4 method for signature 'Hits'
order(..., na.last=TRUE, decreasing=FALSE, method=c("shell", "radix"))
```

#### Arguments

- `x, y, table`  
  Compatible `Hits` objects, that is, `Hits` objects with the same subject and query lengths.
- `nomatch`  
  The value to be returned in the case when no match is found. It is coerced to an integer.
- `incomparables`  
  Not supported.
- `method`  
  For `match`: Use a Quicksort-based (method="quick") or a hash-based (method="hash") algorithm. The latter tends to give better performance, except maybe for some pathological input that we’ve not encountered so far. When method="auto"
is specified, the most efficient algorithm will be used, that is, the hash-based algorithm if `\text{length(x)} \leq 2^{29}`, otherwise the Quicksort-based algorithm.

For order: The method argument is ignored.

... One or more \texttt{Hits} objects. The additional \texttt{Hits} objects are used to break ties.

\texttt{na.last} Ignored.

\texttt{decreasing} TRUE or FALSE.

Details

Only hits that belong to \texttt{Hits} objects with same subject and query lengths can be compared.

\texttt{Hits} are ordered by query hit first, and then by subject hit. On a \texttt{Hits} object, \texttt{order}, \texttt{sort}, and \texttt{rank} are consistent with this order.

\texttt{pcompare(x, y)}: Performs element-wise (aka "parallel") comparison of 2 \texttt{Hits} objects \texttt{x} and \texttt{y}, that is, returns an integer vector where the i-th element is less than, equal to, or greater than zero if \texttt{x[i]} is considered to be respectively less than, equal to, or greater than \texttt{y[i]}. See \texttt{?`Vector-comparison`} for how \texttt{x} or \texttt{y} is recycled when the 2 objects don’t have the same length.

\texttt{match(x, table, nomatch=NA_integer_, method=c("auto", "quick", "hash"))}: Returns an integer vector of the length of \texttt{x}, containing the index of the first matching hit in \texttt{table} (or \texttt{nomatch} if there is no matching hit) for each hit in \texttt{x}.

\texttt{order(...)}: Returns a permutation which rearranges its first argument (a \texttt{Hits} object) into ascending order, breaking ties by further arguments (also \texttt{Hits} objects).

Examples

```r
## A. ELEMENT-WISE (AKA "PARALLEL") COMPARISON OF 2 Hits OBJECTS
## ---------------------------------------------------------------------
hits <- Hits(c(2, 4, 4, 4, 5, 5), c(3, 1, 3, 2, 3, 2), 6, 3)
hits

pcompare(hits, hits[3])
pcompare(hits[3], hits)

hits == hits[3]
hits != hits[3]
hits >= hits[3]
hits < hits[3]

## B. match(), %in%
## ---------------------------------------------------------------------

\texttt{pcompare(x, y)}: Performs element-wise (aka "parallel") comparison of 2 \texttt{Hits} objects \texttt{x} and \texttt{y}, that is, returns an integer vector where the i-th element is less than, equal to, or greater than zero if \texttt{x[i]} is considered to be respectively less than, equal to, or greater than \texttt{y[i]}. See \texttt{?`Vector-comparison`} for how \texttt{x} or \texttt{y} is recycled when the 2 objects don’t have the same length.

\texttt{match(x, table, nomatch=NA_integer_, method=c("auto", "quick", "hash"))}: Returns an integer vector of the length of \texttt{x}, containing the index of the first matching hit in \texttt{table} (or \texttt{nomatch} if there is no matching hit) for each hit in \texttt{x}.

\texttt{order(...)}: Returns a permutation which rearranges its first argument (a \texttt{Hits} object) into ascending order, breaking ties by further arguments (also \texttt{Hits} objects).
table <- hits[-c(1, 3)]
match(hits, table)
hits %in% table

## ---------------------------------------------------------------------
## C. order(), sort(), rank()
## ---------------------------------------------------------------------
order(hits)
sort(hits)
rank(hits)

**Hits-setops**

*Set operations on Hits objects*

**Description**

Perform set operations on Hits objects.

**Details**

union(x, y), intersect(x, y), setdiff(x, y), and setequal(x, y) work on Hits objects x and y only if the objects are compatible Hits objects, that is, if they have the same subject and query lengths. These operations return respectively the union, intersection, (asymmetric!) difference, and equality of the sets of hits in x and y.

**Value**

union returns a Hits object obtained by appending to x the hits in y that are not already in x.

intersect returns a Hits object obtained by keeping only the hits in x that are also in y.

setdiff returns a Hits object obtained by dropping from x the hits that are in y.

setequal returns TRUE if x and y contain the same sets of hits and FALSE otherwise.

union, intersect, and setdiff propagate the names and metadata columns of their first argument (x).

Examples

```r
x <- Hits(c(2, 4, 4, 4, 5, 5), c(3, 1, 3, 2, 3, 2), 6, 3,
          score=11:16)
x

y <- Hits(c(1, 3, 4, 4, 5, 5, 5), c(3, 3, 2, 1, 2, 1, 3), 6, 3,
          score=21:27)
y

union(x, y) # same hits as in union(x, y), but in different order

intersect(x, y) # same hits as in intersect(x, y), but in different order

setdiff(x, y)
setdiff(y, x)

setequal(x, y)
```

---

**HitsList-class**

*List of Hits objects*

**Description**

The HitsList class stores a set of Hits objects. It’s typically used to represent the result of `findOverlaps` on two RangesList objects.

**Details**

Roughly the same set of utilities are provided for HitsList as for Hits:

The `as.matrix` method coerces a HitsList object in a similar way to Hits, except a column is prepended that indicates which space (or element in the query RangesList) to which the row corresponds.

The `as.table` method flattens or unlists the list, counts the number of hits for each query range and outputs the counts as a table, which has the same shape as from a single Hits object.

To transpose a HitsList object `x`, so that the subject and query in each space are interchanged, call `t(x)`. This allows, for example, counting the number of hits for each subject element using `as.table`.

**Accessors**

- `queryHits(x)`: Equivalent to `unname(as.matrix(x)[,1])`.
- `subjectHits(x)`: Equivalent to `unname(as.matrix(x)[,2])`.
- `space(x)`: gets the character vector naming the space in the query RangesList for each hit, or NULL if the query did not have any names.
Coercion

In the code snippets below, \( x \) is a \texttt{HitsList} object.

\begin{itemize}
  \item \texttt{as.matrix(x)}: calls \texttt{as.matrix} on each \texttt{Hits}, combines them row-wise and offsets the indices so that they are aligned with the result of calling \texttt{unlist} on the query and subject.
  \item \texttt{as.table(x)}: counts the number of hits for each query element in \( x \) and outputs the counts as a table, which is aligned with the result of calling \texttt{unlist} on the query.
  \item \texttt{t(x)}: Interchange the query and subject in each space of \( x \), returns a transposed \texttt{HitsList} object.
\end{itemize}

Note

This class is highly experimental. It has not been well tested and may disappear at any time.

- \texttt{findOverlaps} in the \texttt{IRanges} package, which returns a \texttt{HitsList} object when the query and subject are \texttt{RangesList} objects.

\begin{itemize}
  \item \texttt{isSorted} in the \texttt{IRanges} package, which returns a \texttt{HitsList} object when the query and subject are \texttt{RangesList} objects.
\end{itemize}

\begin{itemize}
  \item \texttt{isSorted(x)}
  \item \texttt{isStrictlySorted(x)}
  \item \texttt{isConstant(x)}
\end{itemize}

Arguments

\begin{itemize}
  \item \( x \) A vector-like object. Can also be an array-like object for \texttt{isConstant}.
\end{itemize}

Details

Vector-like objects of length 0 or 1 are always considered to be sorted, strictly sorted, and constant. Strictly sorted and constant objects are particular cases of sorted objects. \texttt{isStrictlySorted(x)} is equivalent to \texttt{isSorted(x) && !anyDuplicated(x)}

Value

A single logical i.e. \texttt{TRUE}, \texttt{FALSE} or \texttt{NA}.
isSorted

Author(s)
Hervé Pagès

See Also

• is.unsorted.
• duplicated and unique.
• all.equal.
• NA and is.finite.

Examples

## ---------------------------------------------------------------------
## A. isSorted() and isStrictlySorted()
## ---------------------------------------------------------------------
x <- 1:10

isSorted(x)    # TRUE
isSorted(-x)   # FALSE
isSorted(rev(x)) # FALSE
isSorted(-rev(x)) # TRUE

isStrictlySorted(x) # TRUE

x2 <- rep(x, each=2)

isSorted(x2)    # TRUE
isStrictlySorted(x2) # FALSE

## ---------------------------------------------------------------------
## B. "isConstant" METHOD FOR integer VECTORS
## ---------------------------------------------------------------------

## On a vector with no NAs:
stopifnot(isConstant(rep(-29L, 10000)))

## On a vector with NAs:
stopifnot(!isConstant(c(0L, NA, -29L)))
stopifnot(is.na(isConstant(c(-29L, -29L, NA))))

## On a vector of length <= 1:
stopifnot(isConstant(NA_integer_))

## ---------------------------------------------------------------------
## C. "isConstant" METHOD FOR numeric VECTORS
## ---------------------------------------------------------------------

## This method does its best to handle rounding errors and special
## values NA, NaN, Inf and -Inf in a way that "makes sense".
## Below we only illustrate handling of rounding errors.

## Here values in 'x' are "conceptually" the same:
x <- c(11/3,
      2/3 + 4/3 + 5/3,
      50 + 11/3 - 50,
      ...)
## List-class

7.00001 - 1000003/300000)

## However, due to machine rounding errors, they are not *strictly*
## equal:
duplicated(x)
unique(x)
## only *nearly* equal:
all.equal(x, rep(11/3, 4))  # TRUE

## 'isConstant(x)' uses 'all.equal()' internally to decide whether
## the values in 'x' are all the same or not:
stopifnot(isConstant(x))

## This is not perfect though:
isConstant((x - 11/3) * 1e8)  # FALSE on Intel Pentium palatforms
    # (but this is highly machine dependent!)

### Description

List objects are Vector objects with a "[", elementType and elementNROWS method. The List
class serves a similar role as list in base R.

It adds one slot, the elementType slot, to the two slots shared by all Vector objects.

The elementType slot is the preferred location for List subclasses to store the type of data repre-
sented in the sequence. It is designed to take a character of length 1 representing the class of the
sequence elements. While the List class performs no validity checking based on elementType, if
a subclass expects elements to be of a given type, that subclass is expected to perform the neces-
sary validity checking. For example, the subclass IntegerList (defined in the IRanges
package) has
elementType = "integer" and its validity method checks if this condition is TRUE.

To be functional, a class that inherits from List must define at least a "[", method (in addition to
the minimum set of Vector methods).

### Construction

List objects are typically constructed using one of the 3 following methods:

- Use of a constructor function. Many constructor functions are provided for List objects e.g.
  List, IntegerList, Rlelist, RangesList, GRangesList, etc... Which one to use depends
  on the particular type of List object to construct. The name of a constructor function is al-
ways the name of a valid class. If it’s the name of a concrete class (e.g. the
GRangesList constructor defined in the GenomicRanges package), then the constructor function returns
an instance of that class. If it’s the name of a virtual class (e.g. the List constructor defined
in this package, or the IntegerList or RleList or RangesList constructors defined in the
IRanges package), then the returned object belongs to a concrete subclass of that virtual class.
Which subclass exactly depends on each constructor function (see man page of a particular
constructor function for the details).

- Coercion to List or to a List subclass. Many coercion methods are provided to turn any object
  into a List object. One general and convenient way to convert any vector-like object into a List
  is to call as(x, "List"). This will typically yield an object from a subclass of Compress-
edList.
• Use of `extractList`. This function, defined in the `{IRanges}` package, extracts user-specified groups of elements from a vector-like object and returns them in a List (or sometimes list) object.

### Accessors

In the following code snippets, `x` is a List object.

- `length(x)`: Get the number of list elements in `x`.
- `names(x), names(x) <- value`: Get or set the names of the elements in the List.
- `mcols(x, use.names=FALSE), mcols(x) <- value`: Get or set the metadata columns. See `Vector` man page for more information.
- `elementType(x)`: Get the scalar string naming the class from which all elements must derive.
- `elementNROWS(x)`: Get the length (or nb of row for a matrix-like object) of each of the elements. Equivalent to `sapply(x, NROW)`.
- `isEmpty(x)`: Returns a logical indicating either if the sequence has no elements or if all its elements are empty.

### Coercion

#### To List.

- `as(x, "List")`: Converts a vector-like object into a List, usually a `CompressedList` derivative. One notable exception is when `x` is an ordinary list, in which case `as(x, "List")` returns a `SimpleList` derivative.
  
  To explicitly request a `SimpleList` derivative, call `as(x, "SimpleList")`.

  See `?CompressedList` (you might need to load the `{IRanges}` package first) and `?SimpleList` for more information about the CompressedList and SimpleList representations.

#### From List. In the code snippets below, `x` is a List object.

- `as.list(x, ...), as(from, "list")`: Turns `x` into an ordinary list.

- `unlist(x, recursive=TRUE, use.names=TRUE)`: Concatenates the elements of `x` into a single vector-like object (of class `elementType(x)`).

- `as.data.frame(x, row.names=NULL, optional=FALSE, value.name="value", use.outer.mcols=FALSE, group_name.as.factor=FALSE, ...)`: Coerces a List to a data.frame. The result has the same length as unlisted `x` with two additional columns, `group` and `group_name`. `group` is an integer that indicates which list element the record came from. `group_name` holds the list name associated with each record; value is character by default and factor when `group_name.as.factor` is TRUE.

  When `use.outer.mcols` is TRUE the metadata columns on the outer list elements of `x` are replicated out and included in the data.frame. List objects that unlist to a single vector (column) are given the column name ‘value’ by default. A custom name can be provided in `value.name`.

  Splitting values in the resulting data.frame by the original groups in `x` should be done using the group column as the `f` argument to `splitToList`. To relist data, use `x` as the skeleton argument to `relist`.
Subsetting

In the code snippets below, `x` is a List object.

- `x[i]`: Return a new List object made of the list elements selected by subscript `i`. Subscript `i` can be of any type supported by subsetting of a Vector object (see Vector man page for the details), plus the following types: `IntegerList`, `LogicalList`, `CharacterList`, `integer-RleList`, `logical-RleList`, `character-RleList`, and `RangesList`. Those additional types perform subsetting within the list elements rather than across them.

- `x[i] <- value`: Replacement version of `x[i]`.

- `x[[i]]`: Return the selected list element `i`, where `i` is an numeric or character vector of length 1.

- `x[[i]] <- value`: Replacement version of `x[[i]]`.

- `x$name`, `x$name <- value`: Similar to `x[[name]]` and `x[[name]] <- value`, but name is taken literally as an element name.

relistToClass

`relistToClass(x)` is the opposite of `elementType(y)` in the sense that the former returns the class of the result of relisting (or splitting) `x` while the latter returns the class of the result of unlisting (or unsplitting) `y`. More formally, if `x` is an object that is relistable and `y` a list-like object:

- `relistToClass(x)` is `class(relist(x, some_skeleton))`
- `elementType(y)` is `class(unlist(y))`

As a consequence, for any object `x` for which `relistToClass(x)` is defined and returns a valid class, `elementType(new(relistToClass(x)))` should return `class(x)`.

Common operations on List objects

Description
Various functions and methods for looping on List objects, functional programming on List objects, and evaluation of an expression in a List object.

Usage

## Looping on List objects:
## ------------------------
##
## S4 method for signature 'List'
lapply(X, FUN, ...)

## S4 method for signature 'List'
sapply(X, FUN, ..., simplify=TRUE, USE_NAMES=TRUE)
endoapply(X, FUN, ...)
revElements(x, i)
mendoapply(FUN, ..., MoreArgs=NULL)

## Functional programming methods for List objects:
## ------------------------------------------------
## S4 method for signature 'List'
Reduce(f, x, init, right=FALSE, accumulate=FALSE)
## S4 method for signature 'List'
Filter(f, x)
## S4 method for signature 'List'
Find(f, x, right=FALSE, nomatch=NULL)
## S4 method for signature 'List'
Map(f, ...)
## S4 method for signature 'List'
Position(f, x, right=FALSE, nomatch=NA_integer_)

## Evaluation of an expression in a List object:
## ---------------------------------------------
## S4 method for signature 'List'
within(data, expr, ...)

## Constructing list matrices:
## ---------------------------------------------
## S4 method for signature 'List'
List-utils

```r
rbind(..., deparse.level=1L)
## S4 method for signature 'List'
cbind(..., deparse.level=1L)
```

**Arguments**

- `X, x` A list, data.frame or `List` object.
- `FUN` The function to be applied to each element of `X` (for `endoapply`) or for the elements in ... (for `mendoapply`).
- `...` For `lapply`, `sapply`, and `endoapply`, optional arguments to `FUN`.
- `for mendoapply`, a set of list, data.frame or `List` objects to compute over.
- `For pc, one or more list-like objects.`
- `For Map, one or more `List` objects. (FIXME: Mixing `List` objects doesn't seem to work properly at the moment.)`
- `simplify, USE.NAMES` See `?base::sapply` for a description of these arguments.
- `MoreArgs` A list of other arguments to `FUN`.
- `i` Index specifying the elements to replace. Can be anything supported by `\[<\]`.
- `f, init, right, accumulate, nomatch` See `?base::Reduce` for a description of these arguments.
- `data` A `List` object.
- `expr` Expression to evaluate.

**Details**

**Looping on List objects:** Like the standard `lapply` function defined in the `base` package, the `lapply` method for `List` objects returns a list of the same length as `X`, with each element being the result of applying `FUN` to the corresponding element of `X`.

Like the standard `sapply` function defined in the `base` package, the `sapply` method for `List` objects is a user-friendly version of `lapply` by default returning a vector or matrix if appropriate.

`endoapply` and `mendoapply` perform the endomorphic equivalents of `lapply` and `mapply` by returning objects of the same class as the inputs rather than a list.

`revElements(x, i)` reverses the list elements in `x` specified by `i`. It’s equivalent to, but faster than, doing `x[i] <- endoapply(x[i], rev)`.

`pc(...)` combines list-like objects in an element-wise fashion. It’s similar to, but faster than, `mapply(c, ..., SIMPLIFY=FALSE)`. With the following differences:
1. `pc()` ignores the supplied objects that are NULL.
2. `pc()` does not recycle its arguments. All the supplied objects must have the same length.
3. If one of the supplied objects is a `List` object, then `pc()` returns a `List` object.
4. `pc()` always returns a homogenous list or `List` object, that is, an object where all the list elements have the same type.

**Functional programming methods for List objects:** The R `base` package defines some higher-order functions that are commonly found in Functional Programming Languages. See `?base::Reduce` for the details, and, in particular, for a description of their arguments. The `S4Vectors` package provides methods for `List` objects, so, in addition to be an ordinary vector or list, the `x` argument can also be a `List` object.
Evaluation of an expression in a List object: within evaluates expr within as.env(data) via eval(data). Similar to with, except assignments made during evaluation are taken as assignments into data, i.e., new symbols have their value appended to data, and assigning new values to existing symbols results in replacement.

Binding Lists into a matrix: There are methods for cbind and rbind that will bind multiple lists together into a basic list matrix. The usual geometric constraints apply. In the future, this might return a List (+ dimensions), but for now the return value is an ordinary list.

Value
endoapply returns an object of the same class as X, each element of which is the result of applying FUN to the corresponding element of X.
mendoapply returns an object of the same class as the first object specified in ..., each element of which is the result of applying FUN to the corresponding elements of ....
pc returns a list or List object of the same length as the input objects.
See ?base::Reduce for the value returned by the functional programming methods.
See ?base::within for the value returned by within.
cbind and rbind return a list matrix.

Author(s)
P. Aboyoun and H. Pagès

Examples
a <- data.frame(x = 1:10, y = rnorm(10))
b <- data.frame(x = 1:10, y = rnorm(10))
endoapply(a, function(x) (x - mean(x))/sd(x))
mendoapply(function(e1, e2) (e1 - mean(e1)) * (e2 - mean(e2)), a, b)
x <- list(a=11:13, b=26:21, c=letters)
y <- list(-(5:1), c("foo", "bar"), 0.25)
pc(x, y)

library(IRanges)
x <- IntegerList(a=11:13, b=26:21, c=31:36, d=4:2)
y <- NumericList(-(5:1), 1:2, numeric(0), 0.25)
pc(x, y)

Reduce("+", x)

Filter(is.unsorted, x)
```r
pos1 <- Position(is.unsorted, x)
stopifnot(identical(Find(is.unsorted, x), x[[pos1]]))

pos2 <- Position(is.unsorted, x, right=TRUE)
stopifnot(identical(Find(is.unsorted, x, right=TRUE), x[[pos2]]))

y <- x * 1000L
Map("c", x, y)

rbind(x, y)
cbind(x, y)
```

### Description

Pairs is a Vector that stores two parallel vectors (any object that can be a column in a DataFrame). It provides conveniences for performing binary operations on the vectors, as well as for converting between an equivalent list representation. Virtually all of the typical R vector operations should behave as expected.

A typical use case is representing the pairing from a `findOverlaps` call, for which `findOverlapPairs` is a shortcut.

### Constructor

```r
Pairs(first, second, ..., names = NULL, hits = NULL): Constructs a Pairs object by aligning the vectors `first` and `second`. The vectors must have the same length, unless `hits` is specified. Arguments in `...` are combined as columns in the `mcols` of the result. The `names` argument specifies the names on the result. If `hits` is not NULL, it should be a `Hits` object that collates the elements in `first` and `second` to produce the corresponding pairs.
```

### Accessors

In the code snippets below, `x` is a Pairs object.

```r
names(x), names(x) <- value: get or set the names
first(x), first(x) <- value: get or set the first member of each pair
second(x), second(x) <- value: get or set the second member of each pair
```

### Coercion

```r
zipup(x): Interleaves the Pairs object `x` into a list, where each element is composed of a pair.
   The type of list depends on the type of the elements.
zipdown(x): The inverse of `zipup()`. Converts `x`, a list where every element is of length 2, to a Pairs object, by assuming that each element of the list represents a pair.
```

### Subsetting

In the code snippets below, `x` is a Pairs object.

```r
x[i]: Subset the Pairs object.
```
**Rle-class**

- **findOverlapPairs** in the **IRanges** package, which generates an instance of this class based on overlaps.
- **setops-methods** in the **IRanges** package, for set operations on Pairs objects.

**Examples**

```r
p <- Pairs(1:10, Rle(1L, 10), score=rnorm(10), names=letters[1:10])
identical(first(p), 1:10)
mcols(p)$score
p
as.data.frame(p)
z <- zipup(p)
first(p) <- Rle(1:10)
identical(zipdown(z), p)
```

---

**Rle-class**

**Rle objects**

**Description**

The **Rle** class is a general container for storing an atomic vector that is stored in a run-length encoding format. It is based on the **rle** function from the base package.

**Constructor**

**Rle(values, lengths):** This constructor creates an **Rle** instance out of an atomic vector or factor object values and an integer or numeric vector **lengths** with all positive elements that represent how many times each value is repeated. The length of these two vectors must be the same. **lengths** can be missing in which case **values** is turned into an **Rle**.

**Getters**

In the code snippets below, **x** is an **Rle** object:

- **runLength(x):** Returns the run lengths for **x**.
- **runValue(x):** Returns the run values for **x**.
- **nrun(x):** Returns the number of runs in **x**.
- **start(x):** Returns the starts of the runs for **x**.
- **end(x):** Returns the ends of the runs for **x**.
- **width(x):** Same as **runLength(x)**.
Rle-class

Setters
In the code snippets below, `x` is an Rle object:

```
runLength(x) <- value: Replaces `x` with a new Rle object using run values `runValue(x)` and run lengths `runLength(x)`.
runValue(x) <- value: Replaces `x` with a new Rle object using run values `value` and run lengths `runLength(x)`.
```

Coercion

From atomic vector to Rle: In the code snippets below, `from` is an atomic vector:
```
as(from, "Rle"): This coercion creates an Rle instances out of an atomic vector `from`.
```

From Rle to other objects: In the code snippets below, `x` and `from` are Rle objects:
```
as.vector(x, mode="any"), as(from, "vector"): Creates an atomic vector based on the values contained in `x`. The vector will be coerced to the requested mode, unless mode is "any", in which case the most appropriate type is chosen.
as.vectorORfactor(x): Creates an atomic vector or factor, based on the type of values contained in `x`. This is the most general way to decompress the Rle to a native R data structure.
as.factor(x), as(from, "factor"): Creates a factor object based on the values contained in `x`.
as.data.frame(x), as(from, "data.frame"): Creates a data.frame with a single column holding the result of as.vector(x).
decode(x): Converts an Rle to its native form, such as an atomic vector or factor. Calling decode on a non-Rle will return `x` by default, so it is generally safe for ensuring that an object is native.
```

General Methods
In the code snippets below, `x` is an Rle object:
```
x[i, drop=getOption("dropRle", default=FALSE)]: Subsets `x` by index `i`, where `i` can be positive integers, negative integers, a logical vector of the same length as `x`, an Rle object of the same length as `x` containing logical values, or an IRanges object. When `drop=FALSE` returns an Rle object. When `drop=TRUE`, returns an atomic vector.
x[i] <- value: Replaces elements in `x` specified by `i` with corresponding elements in `value`. Supports the same types for `i` as `x[i]`.
x %in% table: Returns a logical Rle representing set membership in `table`.
append(x, values, after = length(x)): Insert one Rle into another Rle. values the Rle to insert. after the subscript in `x` after which the values are to be inserted.
c(x, ...): Combines a set of Rle objects.
findRun(x, vec): Returns an integer vector indicating the run indices in Rle `vec` that are referenced by the indices in the integer vector `x`.
head(x, n = 6L): If `n` is non-negative, returns the first `n` elements of `x`. If `n` is negative, returns all but the last `abs(n)` elements of `x`.
is.na(x): Returns a logical Rle indicating with values are NA.
is.unsorted(x, na.rm = FALSE, strictly = FALSE): Returns a logical value specifying if `x` is unsorted.
Rle-class

na.rm remove missing values from check.
strictly check for _strictly_ increasing values.

length(x): Returns the underlying vector length of x.
match(x, table, nomatch = NA_integer_, incomparables = NULL): Matches the values in x to table:
  table the values to be matched against.
nomatch the value to be returned in the case when no match is found.
incomparables a vector of values that cannot be matched. Any value in x matching a value in this vector is assigned the nomatch value.
rep(x, times, length.out, each), rep.int(x, times): Repeats the values in x through one of the following conventions:
times Vector giving the number of times to repeat each element if of length length(x), or to repeat the whole vector if of length 1.
length.out Non-negative integer. The desired length of the output vector.
each Non-negative integer. Each element of x is repeated each times.
rev(x): Reverses the order of the values in x.
show(object): Prints out the Rle object in a user-friendly way.
order(..., na.last = TRUE, decreasing = FALSE, method = c("shell", "radix")): Returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. See order.
sort(x, decreasing = FALSE, na.last = NA): Sorts the values in x.
  decreasing If TRUE, sort values in decreasing order. If FALSE, sort values in increasing order.
  na.last If TRUE, missing values are placed last. If FALSE, they are placed first. If NA, they are removed.
subset(x, subset): Returns a new Rle object made of the subset using logical vector subset.
table(...): Returns a table containing the counts of the unique values. Supported arguments include useNA with values of ‘no’ and ‘ifany’. Multiple Rle’s must be combined with c() before calling table.
tabulate(bin, nbins = max(bin, 1L, na.rm = TRUE)): Just like tabulate, except optimized for Rle.
tail(x, n = 6L): If n is non-negative, returns the last n elements of x. If n is negative, returns all but the first abs(n) elements of x.
unique(x, incomparables = FALSE, ...): Returns the unique run values. The incomparables argument takes a vector of values that cannot be compared with FALSE being a special value that means that all values can be compared.

Set Operations
In the code snippets below, x and y are Rle object or some other vector-like object:
setdiff(x, y): Returns the unique elements in x that are not in y.
union(x, y): Returns the unique elements in either x or y.
intersect(x, y): Returns the unique elements in both x and y.

Examples

x <- Rle(10:1, 1:10)
x

runLength(x)
runValue(x)
nrun(x)

diff(x)
unique(x)
sort(x)
x[c(1,3,5,7,9)]
x > 4

x2 <- Rle(LETTERS[c(21:26, 25:26)], 8:1)
table(x2)

y <- Rle(c(TRUE,TRUE,FALSE,FALSE,TRUE,FALSE,TRUE,TRUE,TRUE))
y
as.vector(y)
rep(y, 10)
c(y, x > 5)

Rle-runstat

Fixed-width running window summaries

Description

The runsum, runmean, runmed, runwtsum, runq functions calculate the sum, mean, median, weighted sum, and order statistic for fixed width running windows.

Usage

runsum(x, k, endrule = c("drop", "constant"), ...)
runmean(x, k, endrule = c("drop", "constant"), ...)

## S4 method for signature 'Rle'
smoothEnds(y, k = 3)

## S4 method for signature 'Rle'
runmed(x, k, endrule = c("median", "keep", "drop", "constant"),
       algorithm = NULL, print.level = 0)
runwtsum(x, k, wt, endrule = c("drop", "constant"), ...)
runq(x, k, i, endrule = c("drop", "constant"), ...)
**Arguments**

- **x**
  - The data object.

- **k**
  - An integer indicating the fixed width of the running window. Must be odd when endrule ! = "drop".

- **endrule**
  - A character string indicating how the values at the beginning and the end (of the data) should be treated.
    - "median" see runmed;
    - "keep" see runmed;
    - "drop" do not extend the running statistics to be the same length as the underlying vectors;
    - "constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant.

- **wt**
  - A numeric vector of length k that provides the weights to use.

- **i**
  - An integer in [0, k] indicating which order statistic to calculate.

- **...**
  - Additional arguments passed to methods. Specifically, na.rm. When na.rm = TRUE, the NA and NaN values are removed. When na.rm = FALSE, NA is returned if either NA or NaN are in the specified window.

**Details**

The runsum, runmean, runmed, runwtsum, and runq functions provide efficient methods for calculating the specified numeric summary by performing the looping in compiled code.

**Value**

An object of the same class as x.

**Author(s)**

P. Aboyoun and V. Obenchain

**See Also**

runmed, Rle-class, RleList-class

**Examples**

```r
x <- Rle(1:10, 1:10)
runsum(x, k = 3)
runsum(x, k = 3, endrule = "constant")
runmean(x, k = 3)
runwtsum(x, k = 3, wt = c(0.25, 0.5, 0.25))
runq(x, k = 5, i = 3, endrule = "constant")
```

```r
## Missing and non-finite values
x <- Rle(c(1, 2, NA, 0, 3, Inf, 4, NaN))
runsum(x, k = 2)
runsum(x, k = 2, na.rm = TRUE)
runmean(x, k = 2, na.rm = TRUE)
runwtsum(x, k = 2, wt = c(0.25, 0.5), na.rm = TRUE)
runq(x, k = 2, i = 2, na.rm = TRUE) ## max value in window
```
## The .naive_runsum() function demonstrates the semantics of runsum(). This test ensures the behavior is consistent with base::sum().

```r
.naive_runsum <- function(x, k, na.rm=FALSE)
  sapply(0:(length(x)-k),
    function(offset) sum(x[1:k + offset], na.rm=na.rm))
```

```r
x0 <- c(1, Inf, 3, 4, 5, NA)
x <- Rle(x0)
target1 <- .naive_runsum(x0, 3, na.rm = TRUE)
target2 <- .naive_runsum(x, 3, na.rm = TRUE)
stopifnot(target1 == target2)
current <- as.vector(runsum(x, 3, na.rm = TRUE))
stopifnot(target1 == current)
```

## runmean() and runwtsum() :

```r
x <- Rle(c(2, 1, NA, 0, 1, -Inf))
runmean(x, k = 3)
runmean(x, k = 3, na.rm = TRUE)
runwtsum(x, k = 3, wt = c(0.25, 0.50, 0.25))
runwtsum(x, k = 3, wt = c(0.25, 0.50, 0.25), na.rm = TRUE)
```

## runq() :

```r
runq(x, k = 3, i = 1, na.rm = TRUE) ## smallest value in window
runq(x, k = 3, i = 3, na.rm = TRUE) ## largest value in window
```

## When na.rm = TRUE, it is possible the number of non-NA values in the window will be less than the 'i' specified.

## Here we request the 4th smallest value in the window, which translates to the value at the 4/5 (0.8) percentile.

```r
x <- Rle(c(1, 2, 3, 4, 5))
runq(x, k=length(x), i=4, na.rm=TRUE)
```

## The same request on a Rle with two missing values finds the value at the 0.8 percentile of the vector at the new length of 3 after the NA's have been removed.

```r
x <- Rle(c(1, 2, 3, NA, NA))
runq(x, k=length(x), i=4, na.rm=TRUE)
```

---

### Rle-utils

#### Common operations on Rle objects

**Description**

Common operations on **Rle** objects.

**Group Generics**

Rle objects have support for S4 group generic functionality:

- **Arith**: `+`, `-`, `*`, `/`, `%%`, `%/%`
- **Compare**: `==`, `>`, `<`, `!=`, `<=`, `>=`
Logic "&", "|

Ops "Arith", "Compare", "Logic"

Math2 "round", "signif"

Summary "max", "min", "range", "prod", "sum", "any", "all"

Complex "Arg", "Conj", "Im", "Mod", "Re"

See S4groupGeneric for more details.

Summary

In the code snippets below, \texttt{x} is an Rle object:

\texttt{summary(object, ..., digits = max(3, getOption("digits") - 3))}: Summarizes the Rle object using an atomic vector convention. The \texttt{digits} argument is used for number formatting with \texttt{signif()}.  

Logical Data Methods

In the code snippets below, \texttt{x} is an Rle object:

\texttt{!x}: Returns logical negation (NOT) of \texttt{x}.

\texttt{which(x)\texttt{}}: Returns an integer vector representing the TRUE indices of \texttt{x}.

Numerical Data Methods

In the code snippets below, \texttt{x} is an Rle object:

\texttt{diff(x, lag = 1, differences = 1)}: Returns suitably lagged and iterated differences of \texttt{x}.

\texttt{pmax(..., na.rm = FALSE), pmax.int(..., na.rm = FALSE)}: Parallel maxima of the Rle input values. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.

\texttt{pmin(..., na.rm = FALSE), pmin.int(..., na.rm = FALSE)}: Parallel minima of the Rle input values. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.

\texttt{which.max(x)}: Returns the index of the first element matching the maximum value of \texttt{x}.

\texttt{mean(x, na.rm = FALSE)}: Calculates the mean of \texttt{x}. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.

\texttt{var(x, y = NULL, na.rm = FALSE)}: Calculates the variance of \texttt{x} or covariance of \texttt{x} and \texttt{y} if both are supplied. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.

\texttt{cov(x, y, use = "everything"), cor(x, y, use = "everything")}: Calculates the covariance and correlation respectively of Rle objects \texttt{x} and \texttt{y}. The \texttt{use} argument is an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete" or "pairwise.complete.obs".

\texttt{sd(x, na.rm = FALSE)}: Calculates the standard deviation of \texttt{x}. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.

\texttt{median(x, na.rm = FALSE)}: Calculates the median of \texttt{x}. Removes \texttt{NA}s when \texttt{na.rm = TRUE}.
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE, names = TRUE, type = 7, ...):
Calculates the specified quantiles of x.
probs A numeric vector of probabilities with values in \([0,1]\).
nan rm If TRUE, removes NAs from x before the quantiles are computed.
names If TRUE, the result has names describing the quantiles.
type An integer between 1 and 9 selecting one of the nine quantile algorithms detailed in quantile.
... Further arguments passed to or from other methods.
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE, low = FALSE, high = FALSE):
Calculates the median absolute deviation of x.
center The center to calculate the deviation from.
constant The scale factor.
nan rm If TRUE, removes NAs from x before the mad is computed.
low If TRUE, compute the 'lo-median'.
high If TRUE, compute the 'hi-median'.
IQR(x, na.rm = FALSE): Calculates the interquartile range of x.
nan rm If TRUE, removes NAs from x before the IQR is computed.
smoothEnds(y, k = 3): Smooth end points of an Rle y using subsequently smaller medians and Tukey’s end point rule at the very end.
k An integer indicating the width of largest median window; must be odd.

Character Data Methods

In the code snippets below, x is an Rle object:

nchar(x, type = "chars", allowNA = FALSE): Returns an integer Rle representing the number of characters in the corresponding values of x.
type One of c("bytes", "chars", "width").
allowNA Should NA be returned for invalid multibyte strings rather than throwing an error?
substr(x, start, stop), substring(text, first, last = 1000000L): Returns a character or factor Rle containing the specified substrings beginning at start/first and ending at stop/last.
chartr(old, new, x): Returns a character or factor Rle containing a translated version of x.
old A character string specifying the characters to be translated.
new A character string specifying the translations.
tolower(x): Returns a character or factor Rle containing a lower case version of x.
toupper(x): Returns a character or factor Rle containing an upper case version of x.
sub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE):
Returns a character or factor Rle containing replacements based on matches determined by regular expression matching. See sub for a description of the arguments.
gsub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE):
Returns a character or factor Rle containing replacements based on matches determined by regular expression matching. See gsub for a description of the arguments.
paste(..., sep = " ", collapse = NULL): Returns a character or factor Rle containing a concatenation of the values in ....
**Factor Data Methods**

In the code snippets below, `x` is an Rle object:

```r
levels(x).levels(x) <- value: Gets and sets the factor levels, respectively.
nlevels(x): Returns the number of factor levels.
```

**Author(s)**

P. Aboyoun

**See Also**

- **Rle objects**
- **S4groupGeneric**

**Examples**

```r
x <- Rle(1:10, 1:10)
x

sqrt(x)
x^2 + 2 * x + 1
range(x)
sum(x)
mean(x)

z <- c("the", "quick", "red", "fox", "jumps", "over", "the", "lazy", "brown", "dog")
z <- Rle(z, seq_len(length(z)))
chartr("a", "@", z)
toupper(z)
```

---

**shiftApply-methods**  
Apply a function over subsequences of 2 vector-like objects

**Description**

The `shiftApply` function loops and applies a function over subsequences of vector-like objects `X` and `Y`.

**Usage**

```r
shiftApply(SHIFT, X, Y, FUN, ..., OFFSET=0L, simplify=TRUE, verbose=FALSE)
```

**Arguments**

- **SHIFT**  
  A non-negative integer vector of shift values.

- **X, Y**  
  The vector-like objects to shift.

- **FUN**  
  The function, found via `match.fun`, to be applied to each set of shifted vectors.

- **...**  
  Further arguments for `FUN`.

- **OFFSET**  
  A non-negative integer offset to maintain throughout the shift operations.

- **simplify**  
  A logical value specifying whether or not the result should be simplified to a vector or matrix if possible.

- **verbose**  
  A logical value specifying whether or not to print the `i` indices to track the iterations.
Details

Let \( i \) be the indices in \( \text{SHIFT}, X_i = \text{window}(X, 1 + \text{OFFSET}, \text{length}(X) - \text{SHIFT}[i]) \), and \( Y_i = \text{window}(Y, 1 + \text{SHIFT}[i], \text{length}(Y) - \text{OFFSET}) \). \text{shiftApply} \) calculates the set of \( \text{FUN}(X_i, Y_i, ...) \) values and returns the results in a convenient form.

See Also

- The \text{window} and \text{aggregate} methods for vector-like objects defined in the \text{S4Vectors} package.
- \text{Vector} and \text{Rle} objects.

Examples

```r
set.seed(0)
lambda <- c(rep(0.001, 4500), seq(0.001, 10, length = 500),
            seq(10, 0.001, length = 500))
xRle <- Rle(rpois(1e7, lambda))
yRle <- Rle(rpois(1e7, lambda[c(251:length(lambda), 1:250)]))

cor(xRle, yRle)
shifts <- seq(235, 265, by=3)
corrs <- shiftApply(shifts, yRle, xRle, FUN=cor)

cor(xRle, yRle)
shiftApply(249:251, yRle, xRle,
          FUN=function(x, y) var(x, y) / (sd(x) * sd(y)))
```

Description

The (non-virtual) SimpleList class extends the \text{List} virtual class.

Details

The SimpleList class is the simplest, most generic concrete implementation of the \text{List} abstraction. It provides an implementation that subclasses can easily extend.

In a SimpleList object the list elements are stored internally in an ordinary list.

Constructor

See the \text{List} man page for a quick overview of how to construct \text{List} objects in general.

The following constructor is provided for SimpleList objects:

\text{SimpleList}(...) \: \text{Take}s possibly named objects as elements for the new SimpleList object.

Accessors

Same as for \text{List} objects. See the \text{List} man page for more information.

Coercion

All the coercions documented in the \text{List} man page apply to SimpleList objects.
split-methods

Divide a vector-like object into groups

**Description**

split divides the data in a vector-like object x into the groups defined by f.

NOTE: This man page is for the split methods defined in the S4Vectors package. See ?base::split for the default method (defined in the base package).
Usage

```r
## S4 method for signature 'Vector,ANY'
split(x, f, drop=FALSE)

## S4 method for signature 'ANY,Vector'
split(x, f, drop=FALSE)

## S4 method for signature 'Vector,Vector'
split(x, f, drop=FALSE)

## S4 method for signature 'list,Vector'
split(x, f, drop=FALSE, ...)
```

Arguments

- `x`, `f` - 2 vector-like objects of the same length. `f` will typically be a factor, but not necessarily.
- `drop` - Logical indicating if levels that do not occur should be dropped (if `f` is a factor).
- `...` - Arguments passed to `base::split` (see Details below).

Details

The first 3 methods just delegate to the `IRanges::splitAsList` function defined in the `IRanges` package.

The method for `list` does:

```r
split(x, as.vector(f), drop=drop, ...)
```

Value

All these methods behave like `base::split` except that the first 3 methods return a `List` object instead of an ordinary list.

See Also

- The `split` function in the `base` package.
- The `splitAsList` function in the `IRanges` package.
- `Vector` and `List` objects.
- `Rle` and `DataFrame` objects.

Examples

```r
## On an Rle object:
 x <- Rle(101:105, 6:2)
 split(x, c("B", "B", "A", "B", "A"))

## On a DataFrame object:
groups <- c("group1", "group2")
DF <- DataFrame(
   =letters[3:10],
   i=101:110,
   group=rep(factor(groups, levels=groups), c(3, 7))
```
str-utils

Description

Some low-level string utilities that operate on ordinary character vectors. For more advanced string manipulations, see the Biostrings package.

Usage

unstrsplit(x, sep="") # 'sep' default is "" (empty string)

strsplitAsListOfIntegerVectors(x, sep=",") # 'sep' default is ","

Arguments

x
  For unstrsplit: A list-like object where each list element is a character vector, or a character vector (identity).
  For strsplitAsListOfIntegerVectors: A character vector where each element is a string containing comma-separated decimal integer values.

sep
  A single string containing the separator character. For strsplitAsListOfIntegerVectors, the separator must be a single-byte character.

Details

unstrsplit: unstrsplit(x, sep) is equivalent to (but much faster than) sapply(x, paste0, collapse=sep).
It's performing the reverse transformation of strsplit( , fixed=TRUE), that is, if x is a character vector with no NAs and sep a single string, then unstrsplit(strsplit(x, split=sep, fixed=TRUE), sep) is identical to x. A notable exception to this though is when strsplit finds a match at the end of a string, in which case the last element of the output (which should normally be an empty string) is not returned (see ?strsplit for the details).

strsplitAsListOfIntegerVectors: strsplitAsListOfIntegerVectors is similar to the strsplitAsListOfIntegerVectors2 function shown in the Examples section below, except that the former generally raises an error where the latter would have inserted an NA in the returned object. More precisely:
  • The latter accepts NAs in the input, the former doesn’t (raises an error).
  • The latter introduces NAs by coercion (with a warning), the former doesn’t (raises an error).
  • The latter supports "inaccurate integer conversion in coercion" when the value to coerce is > INT_MAX (then it’s coerced to INT_MAX), the former doesn’t (raises an error).
  • The latter coerces non-integer values (e.g. 10.3) to an int by truncating them, the former doesn’t (raises an error).
When it fails, strsplitAsListOfIntegerVectors will print an informative error message. Finally, strsplitAsListOfIntegerVectors is faster and uses much less memory than strsplitAsListOfIntegerVectors2.

Value

unstrsplit returns a character vector with one string per list element in x.
strsplitAsListOfIntegerVectors returns a list where each list element is an integer vector. There is one list element per string in x.

Examples

```r
data(islands)
x <- names(islands)
y <- strsplit(x, split=" ", fixed=TRUE)
x2 <- unstrsplit(y, sep=" ")
stopifnot(identical(x, x2))
```

```r
y[x != x2]
## In other words: strsplit() behavior sucks :-/
```

```r
y <- strsplitAsListOfIntegerVectors(x)
y
```

```r
y2 <- strsplitAsListOfIntegerVectors2(x)
stopifnot(identical(y, y2))
```

```r
```
**Description**

Low-level utility functions and classes defined in the S4Vectors package to support subsetting of vector-like objects. They are not intended to be used directly.

**Vector-class**

*Vector objects*

**Description**

The Vector virtual class serves as the heart of the S4Vectors package and has over 90 subclasses. It serves a similar role as vector in base R.

The Vector class supports the storage of *global* and *element-wise* metadata:

1. The *global* metadata annotates the object as a whole: this metadata is accessed via the `metadata` accessor and is represented as an ordinary list;
2. The *element-wise* metadata annotates individual elements of the object: this metadata is accessed via the `mcols` accessor (`mcols` stands for *metadata columns*) and is represented as a `DataTable` object (i.e. as an instance of a concrete subclass of `DataTable`, e.g. a `DataFrame` object), with a row for each element and a column for each metadata variable. Note that the element-wise metadata can also be `NULL`.

To be functional, a class that inherits from Vector must define at least a `length` and a `"["` method.

**Accessors**

In the following code snippets, `x` is a Vector object.

- `length(x)`: Get the number of elements in `x`.
- `lengths(x, use.names=TRUE)`: Get the length of each of the elements.
  
  Note: The `lengths` method for Vector objects is currently defined as an alias for `elementNROWS` (with addition of the `use.names` argument), so is equivalent to `sapply(x, NROW)`, not to `sapply(x, length)`. See `?BiocGenerics::lengths` in the `BiocGenerics` package for more information about this.

- `NROW(x)`: Defined as `length(x)` for any Vector object that is *not* a `DataTable` object. If `x` is a `DataTable` object, then it's defined as `nrow(x)`.

- `names(x), names(x) <- value`: Get or set the names of the elements in the Vector.

- `rename(x, value, ...)`: Replace the names of `x` according to a mapping defined by a named character vector, formed by concatenating value with any arguments in .... The names of the character vector indicate the source names, and the corresponding values the destination names. This also works on a plain old vector.

- `nlevels(x)`: Returns the number of factor levels.

- `mcols(x, use.names=FALSE), mcols(x) <- value`: Get or set the metadata columns. If `use.names=TRUE` and the metadata columns are not NULL, then the names of `x` are propagated as the row names of the returned `DataTable` object. When setting the metadata columns, the supplied value must be `NULL` or a `DataTable` object holding element-wise metadata.

- `elementMetadata(x, use.names=FALSE), elementMetadata(x) <- value, values(x, use.names=FALSE), values(x) <- value`: Alternatives to `mcols` functions. Their use is discouraged.
Coercion

\texttt{as(from, "data.frame"), as.data.frame(from)}: Coerces from a Vector to a \texttt{data.frame} by first coercing the Vector to a vector via \texttt{as.vector}. Note that many Vector derivatives do not support \texttt{as.vector}, so this coercion is possible only for certain types.

\texttt{as.env(x)}: Constructs an environment object containing the elements of \texttt{mcols(x)}.

Subsetting

In the code snippets below, \texttt{x} is a Vector object or regular R vector object. The R vector object methods for \texttt{window} are defined in this package and the remaining methods are defined in base R.

\texttt{x[i, drop=TRUE]}: If defined, returns a new Vector object made of selected elements \texttt{i}, which can be missing; an NA-free logical, numeric, or character vector; or a logical Rle object. The \texttt{drop} argument specifies whether or not to coerce the returned sequence to an ordinary vector.

\texttt{x[i] <- value}: Replacement version of \texttt{x[i]}.

Combining

In the code snippets below, \texttt{x} is a Vector object.

\texttt{c(x, ...)}: Combine \texttt{x} and the Vector objects in \texttt{...} together. Any object in \texttt{...} must belong to the same class as \texttt{x}, or to one of its subclasses, or must be \texttt{NULL}. The result is an object of the same class as \texttt{x}.

\texttt{append(x, values, after = length(x))}: Insert the Vector values onto \texttt{x} at the position given by \texttt{after}. \texttt{values} must have an \texttt{elementType} that extends that of \texttt{x}.

Displaying

FOR ADVANCED USERS OR DEVELOPERS Displaying of a Vector object is controlled by 2 internal helpers, \texttt{classNameForDisplay} and \texttt{showAsCell}.

For most objects \texttt{classNameForDisplay(x)} just returns \texttt{class(x)}. However, for some objects it can return the name of a parent class that is more suitable for display because it’s simpler and as informative as the real class name. See \texttt{SimpleList} objects (defined in this package) and \texttt{CompressedList} objects (defined in the \texttt{IRanges} package) for examples of objects for which \texttt{classNameForDisplay} returns the name of a parent class.

\texttt{showAsCell(x)} produces a character vector \textit{parallel} to \texttt{x} (i.e. with one string per vector element in \texttt{x}) that contains compact string representations of each elements in \texttt{x}.

Note that \texttt{classNameForDisplay} and \texttt{showAsCell} are generic functions so developers can implement methods to control how their own Vector extension gets displayed.

See Also

- \texttt{Vector-comparison} for comparing, ordering, and tabulating vector-like objects.
- \texttt{Vector-setops} for set operations on vector-like objects.
- \texttt{Vector-merge} for merging vector-like objects.
- \texttt{List} for a direct Vector extension that serves a similar role as \texttt{list} in base R.
- \texttt{extractList} for grouping elements of a vector-like object into a list-like object.
- \texttt{DataTable} which is the type of objects returned by the \texttt{mcols} accessor.
- The \texttt{Annotated} class, which Vector extends.
Examples

```
showClass("Vector")  # shows (some of) the known subclasses
```

Vector-comparison  Compare, order, tabulate vector-like objects

Description

Generic functions and methods for comparing, ordering, and tabulating vector-like objects.

Usage

```
## Element-wise (aka "parallel") comparison of 2 Vector objects
## -------------------------------------------------------------

pcompare(x, y)

## S4 method for signature 'Vector,Vector'
e1 == e2

## S4 method for signature 'Vector,ANY'
e1 == e2

## S4 method for signature 'ANY,Vector'
e1 == e2

## S4 method for signature 'Vector,Vector'
e1 <= e2

## S4 method for signature 'Vector,ANY'
e1 <= e2

## S4 method for signature 'ANY,Vector'
e1 <= e2

## S4 method for signature 'Vector,Vector'
e1 != e2

## S4 method for signature 'Vector,ANY'
e1 != e2

## S4 method for signature 'ANY,Vector'
e1 != e2

## S4 method for signature 'Vector,Vector'
e1 >= e2

## S4 method for signature 'Vector,ANY'
e1 >= e2

## S4 method for signature 'ANY,Vector'
e1 >= e2

## S4 method for signature 'Vector,Vector'
e1 < e2

## S4 method for signature 'Vector,ANY'
e1 < e2

## S4 method for signature 'ANY,Vector'
```
e1 < e2

## S4 method for signature 'Vector,Vector'
e1 > e2

## S4 method for signature 'Vector,ANY'
e1 > e2

## S4 method for signature 'ANY,Vector'
e1 > e2

## selfmatch()
## ------------------------
selfmatch(x, ...)

## duplicated() & unique()
## ------------------------

## S4 method for signature 'Vector'
duplicated(x, incomparables=FALSE, ...)

## S4 method for signature 'Vector'
unique(x, incomparables=FALSE, ...)

## %in%
## ------

## S4 method for signature 'Vector,Vector'
x %in% table

## S4 method for signature 'Vector,ANY'
x %in% table

## S4 method for signature 'ANY,Vector'
x %in% table

## findMatches() & countMatches()
## -------------------------------
findMatches(x, table, select=c("all", "first", "last"), ...)
countMatches(x, table, ...)

## sort()
## ------

## S4 method for signature 'Vector'
sort(x, decreasing=FALSE, na.last = NA, by)

## table()
## -------

## S4 method for signature 'Vector'
table(...)

Vector-comparison
Arguments

x, y, e1, e2, table

Vector-like objects.

incomparables

The duplicated method for Vector objects does NOT support this argument.
The unique method for Vector objects, which is implemented on top of duplicated, propagates this argument to its call to duplicated.
See ?base::duplicated and ?base::unique for more information about this argument.

select

Only select="all" is supported at the moment. Note that you can use match if you want to do select="first". Otherwise you’re welcome to request this on the Bioconductor mailing list.

decreasing, na.last

See ?base::sort.

by

A formula referencing the metadata columns by which to sort, e.g., ~ x + y sorts by column “x”, breaking ties with column “y”.

... A Vector object for table (the table method for Vector objects can only take one input object).

Otherwise, extra arguments supported by specific methods. In particular:

• The default selfmatch method, which is implemented on top of match, propagates the extra arguments to its call to match.

• The duplicated method for Vector objects, which is implemented on top of selfmatch, accepts extra argument fromLast and propagates the other extra arguments to its call to selfmatch. See ?base::duplicated for more information about this argument.

• The unique method for Vector objects, which is implemented on top of duplicated, propagates the extra arguments to its call to duplicated.

• The default findMatches and countMatches methods, which are implemented on top of match and selfmatch, propagate the extra arguments to their calls to match and selfmatch.

• The sort method for Vector objects, which is implemented on top of order, only accepts extra argument na.last and propagates it to its call to order.

Details

Doing pcompare(x, y) on 2 vector-like objects x and y of length 1 must return an integer less than, equal to, or greater than zero if the single element in x is considered to be respectively less than, equal to, or greater than the single element in y. If x or y have a length != 1, then they are typically expected to have the same length so pcompare(x, y) can operate element-wise, that is, in that case it returns an integer vector of the same length as x and y where the i-th element is the result of comparing x[i] and y[i]. If x and y don’t have the same length and are not zero-length vectors, then the shortest is first recycled to the length of the longest. If one of them is a zero-length vector then pcompare(x, y) returns a zero-length integer vector.

selfmatch(x, ...) is equivalent to match(x, x, ...). This is actually how the default method is implemented. However note that selfmatch(x, ...) will typically be more efficient than match(x, x, ...) on vector-like objects for which a specific selfmatch method is implemented. findMatches is an enhanced version of match which, by default (i.e. if select="all"), returns all the matches in a Hits object.

countMatches returns an integer vector of the length of x containing the number of matches in table for each element in x.
Value

For pcompare: see Details section above.
For selfmatch: an integer vector of the same length as x.
For duplicated, unique, and %in%: see ?BiocGenerics::duplicated, ?BiocGenerics::unique, and ?%in%.
For findMatches: a Hits object by default (i.e. if select="all").
For countMatches: an integer vector of the length of x containing the number of matches in table for each element in x.
For sort: see ?BiocGenerics::sort.
For table: a 1D array of integer values promoted to the "table" class. See ?BiocGenerics::table for more information.

Note

The following notes are for developers who want to implement comparing, ordering, and tabulating methods for their own Vector subclass:

1. The 6 traditional binary comparison operators are: ==, !=, <=, >=, <, and >. The S4Vectors package provides the following methods for these operators:

   ```r
   setMethod("==", c("Vector", "Vector"),
       function(e1, e2) { pcompare(e1, e2) == 0L } )
   setMethod("<=", c("Vector", "Vector"),
       function(e1, e2) { pcompare(e1, e2) <= 0L } )
   setMethod("!="", c("Vector", "Vector"),
       function(e1, e2) { !(e1 == e2) } )
   setMethod(">=", c("Vector", "Vector"),
       function(e1, e2) { e2 <= e1 } )
   setMethod("<", c("Vector", "Vector"),
       function(e1, e2) { !(e2 <= e1) } )
   setMethod(">", c("Vector", "Vector"),
       function(e1, e2) { !(e1 <= e2) } )
   ```

   With these definitions, the 6 binary operators work out-of-the-box on Vector objects for which pcompare works the expected way. If pcompare is not implemented, then it’s enough to implement == and <= methods to have the 4 remaining operators (!=, >=, <, and >) work out-of-the-box.

2. The S4Vectors package provides no pcompare method for Vector objects. Specific pcompare methods need to be implemented for specific Vector subclasses (e.g. for Hits and Ranges objects). These specific methods must obey the rules described in the Details section above.

3. The duplicated, unique, and %in% methods for Vector objects are implemented on top of selfmatch, duplicated, and match, respectively, so they work out-of-the-box on Vector objects for which selfmatch, duplicated, and match work the expected way.
4. Also the default findMatches and countMatches methods are implemented on top of match and selfmatch so they work out-of-the-box on Vector objects for which those things work the expected way.

5. However, since selfmatch itself is also implemented on top of match, then having match work the expected way is actually enough to get selfmatch, duplicated, unique, %in%, findMatches, and countMatches work out-of-the-box on Vector objects.

6. The sort method for Vector objects is implemented on top of order, so it works out-of-the-box on Vector objects for which order works the expected way.

7. The table method for Vector objects is implemented on top of selfmatch, order, and as.character, so it works out-of-the-box on a Vector object for which those things work the expected way.

8. The S4Vectors package provides no match or order methods for Vector objects. Specific methods need to be implemented for specific Vector subclasses (e.g. for Hits and Ranges objects).

Examples

```r
## ---------------------------------------------------------------------
## A. SIMPLE EXAMPLES
## ---------------------------------------------------------------------

y <- c(16L, -3L, -2L, 15L, 15L, 0L, 8L, 15L, -2L)
selmatch(y)

x <- c(unique(y), 999L)
findMatches(x, y)
countMatches(x, y)

## See '?Ranges-comparison' for more examples (on Ranges objects). You
## might need to load the IRanges package first.

## ---------------------------------------------------------------------
## B. FOR DEVELOPERS: HOW TO IMPLEMENT THE BINARY COMPARISON OPERATORS
## Accessed via
```
## FOR YOUR Vector SUBCLASS
#
## The answer is: don’t implement them. Just implement pcompare() and the
## binary comparison operators will work out-of-the-box. Here is an
## example:

## (1) Implement a simple Vector subclass.

```
setClass("Raw", contains="Vector", representation(data="raw"))
setMethod("length", "Raw", function(x) length(x@data))
setMethod("[", "Raw",
  function(x, i, j, ..., drop) { x@data <- x@data[i]; x }
)
x <- new("Raw", data=charToRaw("AB.x0a-BAA+C"))
stopifnot(identical(length(x), 12L))
stopifnot(identical(x[7:3], new("Raw", data=charToRaw("-a0x."))))
```

## (2) Implement a "pcompare" method for Raw objects.

```
setMethod("pcompare", c("Raw", "Raw"),
  function(x, y) {as.integer(x@data) - as.integer(y@data)}
)
```

```
stopifnot(identical(which(x == x[1]), c(1L, 9L, 10L)))
stopifnot(identical(x[x < x[5]], new("Raw", data=charToRaw(".-++"))))
```

---

### Vector-merge

#### Merge vector-like objects

**Description**

A merge method for vector-like objects.

**Usage**

```
merge(x, y, ..., all=FALSE, all.x=NA, all.y=NA, sort=TRUE)
```

**Arguments**

- `x, y, ...` Vector-like objects, typically all of the same class and typically not list-like objects (even though some list-like objects like `Ranges` and `DNAStringSet` are supported). Duplicated elements in each object are removed with a warning.
- `all` TRUE or FALSE. Whether the vector elements in the result should be the union (when `all=TRUE`) or intersection (when `all=FALSE`) of the vector elements in `x`, `y`, ...
- `all.x, all.y` To be used only when merging 2 objects (binary merge). Both `all.x` and `all.y` must be single logicais. If any of them is `NA`, then it’s set to the value of `all`. 

Setting both of them to TRUE or both of them to FALSE is equivalent to setting all to TRUE or to FALSE, respectively (see above).
If all.x is TRUE and all.y is FALSE then the vector elements in the result will be the unique elements in x. If all.x is FALSE and all.y is TRUE then the vector elements in the result will be the unique elements in y.

```
sort
```
Whether to sort the merged result.

**Details**

This merge method acts much like `merge.data.frame`, except for 3 important differences:

1. The matching is based on the vector values, not arbitrary columns in a table.
2. Self merging is a no-op if `sort=FALSE` (or object already sorted) and if the object has no duplicates.
3. This merge method accepts an arbitrary number of vector-like objects (n-ary merge).

If some of the objects to merge are list-like objects not supported by the method described here, then the merging is simply done by calling `base::merge()` on the objects. This might succeed or not...

**Value**

A vector-like object of the same class as the input objects (if they all have the same class) containing the merged vector values and metadata columns.

**See Also**

- The Vector class.
- Vector-comparison for comparing and ordering vector-like objects.
- Vector-setops for set operations on vector-like objects.

**Examples**

```r
library(GenomicRanges)
x <- GRanges(c("chr1:1-1000", "chr2:2000-3000"),
            score=c(0.45, 0.1), a1=c(5L, 7L), a2=c(6, 8))
y <- GRanges(c("chr2:150-151", "chr1:1-10", "chr2:2000-3000"),
            score=c(0.7, 0.82, 0.1), b1=c(0L, 5L, 1L), b2=c(1, -2, 1))
merge(x, y)
merge(x, y, all=TRUE)
merge(x, y, all.x=TRUE)
merge(x, y, all.y=TRUE)
```

```r
## Shared metadata columns must agree:
mcols(x)$score[2] <- 0.11
#merge(x, y) # error!
```

```r
## NAs agree with anything:
mcols(x)$score[2] <- NA
merge(x, y)
```

```r
## NAs agree with anything:
mcols(x)$score[2] <- NA
merge(x, y)
```
Set operations on vector-like objects

Description

Perform set operations on Vector objects.

Usage

```r
## S4 method for signature 'Vector,Vector'
union(x, y)
## S4 method for signature 'Vector,Vector'
intersect(x, y)
## S4 method for signature 'Vector,Vector'
setdiff(x, y)
## S4 method for signature 'Vector,Vector'
setequal(x, y)
```

Arguments

- `x`, `y` Vector-like objects.

Details

The union, intersect, and setdiff methods for Vector objects return a Vector object containing respectively the union, intersection, and (asymmetric!) difference of the 2 sets of vector elements in `x` and `y`. The setequal method for Vector objects checks for set equality between `x` and `y`.

They’re defined as follow:

```r
setMethod("union", c("Vector", "Vector"),
  function(x, y) unique(c(x, y))
)
setMethod("intersect", c("Vector", "Vector"),
  function(x, y) unique(x[x %in% y])
)
setMethod("setdiff", c("Vector", "Vector"),
  function(x, y) unique(x[!(x %in% y)])
)
setMethod("setequal", c("Vector", "Vector"),
  function(x, y) all(x %in% y) && all(y %in% x)
)
```

so they work out-of-the-box on Vector objects for which `c`, `unique`, and `%in%` are defined.
zip-methods

Value

union returns a Vector object obtained by appending to x the elements in y that are not already in x.
intersect returns a Vector object obtained by keeping only the elements in x that are also in y.
setdiff returns a Vector object obtained by dropping from x the elements that are in y.
setequal returns TRUE if x and y contain the same sets of vector elements and FALSE otherwise.
union, intersect, and setdiff propagate the names and metadata columns of their first argument (x).

zip-methods

Convert between parallel vectors and lists

Description

The zipup and zipdown functions convert between two parallel vectors and a list of doublets (elements of length 2). The metaphor, borrowed from Python’s zip, is that of a zipper. The zipup function interleaves the elements of the parallel vectors into a list of doublets. The inverse operation is zipdown, which returns a Pairs object.

Usage

```r
zipup(x, y, ...)
zipdown(x, ...)
```

Arguments

- `x, y` For zipup, any vector-like object. For zipdown, a doublet list.
- `...` Arguments passed to methods.

Value

For zipup, a list-like object, where every element is of length 2. For zipdown, a Pairs object.
See Also

- Pairs objects.

Examples

```r
z <- zipup(1:10, Rle(1L, 10))
pairs <- zipdown(z)
```
