convertAAP-package  Converting an alignment into a matrix using the AAP encoding

Description

Convert an alignment read in by seqinr into a matrix using the AAP encoding. This is suitable for BGA analysis using PCA.

Details

Package: convertAAP
Type: Package
Version: 1.0
Date: 2007-03-14
License: Artistic License

add_pseudo_counts Add pseudo counts to amino acid matrix based on defined groups

Description
This function will add pseudo counts to binary amino acid matrix based on the defined groups. It is used to minimise the effect of small sample size. The method of Henikoff and Henikoff is used to calculate the pseudocounts. An alternative method is to simply add 1 to the binary matrix.

Usage
add_pseudo_counts(amino, groups)

Arguments
amino Matrix representation of alignment generated by convert_aln_amino
groups Vector or factor that shows the group representation for each sequence in the alignment

Examples
library(bgafun)
data(LDH.amino.gapless)
data(LDH.groups)
LDH.pseudo=LDH.amino.gapless+1
#or use the function
LDH.pseudo=add_pseudo_counts(LDH.amino.gapless,LDH.groups)

amino_counts calculate count of amino acid types at each position

Description
Internal Function Calculate the counts of amino acid types at each position in an alignment from a binary amino acid matrix.
average_cols_aap \hspace{1cm} \textit{Replaces gaps with the average of the column}

\textbf{Description}

This function will deal with gaps in the Amino Acid Property encoding scheme. It replaces gaps with the average in the column for each group, provided the column is highly occupied for that group. It will only average out over columns that have high percentage of gaps. It will remove all other columns containing gaps.

\textbf{Usage}

\begin{verbatim}
average_cols_aap(x,y)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
\item \texttt{x} \hspace{1cm} Matrix representation of alignment generated by \texttt{convert_aln_AAP}
\item \texttt{y} \hspace{1cm} Vector or factor that shows the group representation for each sequence in the alignment
\end{itemize}

\textbf{Examples}

\begin{verbatim}
library(bgafun)
data(LDH)
data(LDH.groups)
LDH.aap=convert_aln_AAP(LDH)
LDH.aap.ave=average_cols_aap(LDH.aap,LDH.groups)
dim(LDH.aap.ave)
\end{verbatim}

\textbf{BGAfun} \hspace{1cm} \textit{BGAfun A method to identify specificity determining residues in protein families}

\textbf{Description}

This Package combines between group analysis with sequence alignments to identify specificity determining residues in protein families.

\textbf{Author(s)}

Iain Wallace <iain.wallace@ucd.ie>

\textbf{References}

**calculate_pseudo**

**Examples**

```r
library(bgafun)
#read in alignment
LDH <- read.alignment(file = system.file("sequences/LDH-MDH-PF00056.fasta", package = "bgafun"), format = "fastafile")

#Assign into groups
LDH.amino=convert_aln_amino(LDH)
LDH.groups=rownames(LDH.amino)
LDH.groups[grepl("LDH",LDH.groups)]="LDH"
LDH.groups[grepl("MDH",LDH.groups)]="MDH"
LDH.groups=as.factor(LDH.groups)

#Convert to Amino Acid matrix (or Amino Acid properties matrix)
LDH.amino.gapless=remove_gaps_groups(LDH.amino,LDH.groups)

#Add Psuedo counts
LDH.pseudo=LDH.amino.gapless+1

LDH.binary.bga=bga(t(LDH.pseudo),LDH.groups)
plot(LDH.binary.bga)
```

**calculate_pseudo**

*Calculates pseudo count for each column in the amino acid matrix*

**Description**

Internal function Calculates the pseudo count for each column in the amino acid matrix

**Calculate_Row_Weights**

*Calculate the sequence weights for all the rows in my amino, using label as the grouping*

**Description**

This will calculate the sequence weights for each group using the Heinkoff and Heinkoff method. Each residue in the sequence is assigned a weight depending on how unique it is in the column. The sequence weight is then the sum of these weights, and the total weight is the number of groups

**Usage**

`Calculate_Row_Weights(my_amino,label)`

**Arguments**

- `my_amino` Matrix representation of alignment generated by `convert_align_amino`
- `label` Vector or factor that shows the group representation for each sequence in the alignment
convert_aln_AAP

Converts alignment into a matrix using the amino acid property encoding

Description

Each residue in the alignment is represented by a vector of five continuous variables as given by Atchley et al. They applied a multivariate statistic approach to reduce the information in 494 amino acid attributes into a set of five factors for each amino acid. Factor A is termed the polarity index. It correlates well with a large variety of descriptors including the number of hydrogen bond donors, polarity versus nonpolarity, and hydrophobicity versus hydrophilicity. Factor B is a secondary structure index. It represents the propensity of an amino acid to be in a particular type of secondary structure, such as a coil, turn or bend versus the frequency of it in an α-helix. Factor C is correlated with molecular size, volume and molecular weight. Factor D reflects the number of codons coding for an amino acid and amino acid composition. These attributes are related to various physical properties including refractivity and heat capacity. Factor E is related to the electrostatic charge. Gaps are represented by five zeros and should be either removed or replaced by the average of the column for a particular group.

Usage

convert_aln_AAP(Alignment)

Arguments

Alignment Alignment object read in using read.alignment function in seqinr

References

Examples

library(bgafun)
data(LDH)
data(LDH.groups)
LDH.aap=convert_aln_AAP(LDH)
dim(LDH.aap)
LDH.aap.ave=average_cols_aap(LDH.aap,LDH.groups)
dim(LDH.aap.ave)
**convert_aln_amino**

Converts an alignment object into binary amino matrix

**Description**

Converts an alignment object, read in by the seqinr package, into a binary matrix. The binary matrix represents the absence or presence of amino acids at each position in the alignment.

**Usage**

```r
convert_aln_amino(Alignment)
```

**Arguments**

- **Alignment**: Alignment object read in using read.alignment function in seqinr

**Examples**

```r
library(bgafun)
LDH <- read.alignment(file = system.file("sequences/LDH-MDH-PF00056.fasta", package = "bgafun"), format = "fasta")
LDH.amino=convert_aln_amino(LDH)
dim(LDH.amino)
```

**convert_seq_amino**

Converts a single sequence into a binary string

**Description**

Internal Function Converts a single sequence from an alignment object into a binary string

**create_colnames_amino**

Creates the column names for the binary matrix

**Description**

Internal Function Creates the column names for the matrix in the form "Position""Amino Acid Letter"

**create_probab**

Generates probability matrix for pseudocounts calculation

**Description**

Internal function. Generates an amino acid probability matrix which is based on BLOSUM 62, and is used to calculate how many pseudo counts should be added.
create_profile

Creates a sequence profile for a binary amino acid matrix

Description

Internal Function Returns a profile matrix, which show how many of each type of amino acids are in each position in an alignment. It takes in a binary amino acid matrix.

create_profile_strings

Create a profile string for each group in an alignment

Description

This function is used to analysis the amino acids at each position in the alignment. It can be used to analysis the columns that the bga analysis identified as interesting. It creates a profile string, 1D vector which shows the number of amino acids at each position in an alignment for each group that has been defined.

Usage

create_profile_strings(x, y)

Arguments

x Matrix representation of alignment generated by convert\_aln\_amino

y Vector or factor that shows the group representation for each sequence in the alignment

Examples

library(bgafun)
data(LDH.groups)
data(LDH.amino.gapless)
#run the analysis
LDH.binary.bga=bga(t(LDH.amino.gapless+1),LDH.groups)
#Get the important residues
top_res=top_residues_2_groups(LDH.binary.bga)
#To tidy up the results
names(top_res)=sub("X","",names(top_res))
# and now look at the amino acid content in the alignment
LDH.profiles=create_profile_strings(LDH.amino.gapless,LDH.groups)
# and now look at only those columns that are identified by BGA
#LDH.profiles[,,(colnames(LDH.profiles) %in% names(top_res))]
### Henikoff_weights

*Calculates Henikoff weights for each sequence in a binary amino acid matrix*

#### Description

Internal Function Calculates a sequence weight for each sequence in an alignment using the Henikoff method.

#### References

### LDH

*LDH alignment read in from a file*

#### Description

Seqinr representation of the LDH example alignment.

### LDH.aap

*AAP matrix*

#### Description

Amino Acid Propties representation of LDH alignment

### LDH.aap.ave

*AAP matrix*

#### Description

Amino Acid Properties Matrix after averaging out gaps

### LDH.amino

*Binary amino acid matrix after converting the Lactate alignment*

#### Description

Binary amino acid matrix after converting the Lactate alignment
### Description

The amino acid matrix for the lactate example, after removing gappy positions

### Usage

```r
data(LDH.amino.pseudo)
```

### LDH.groups

*Groups in the LDH alignment*

Factor assigning the sequences in the LDH alignment into one of two groups

### pseudo_counts

*Calculate pseudo counts for a profile*

Internal function that is used to calculate pseudo counts for an amino acid profile. The Henikoff method is used.

### remove_gaps

*Removes gaps from a amino binary matrix*

Internal Function This removes gappy positions from an alignment represented in a binary matrix.
remove_gaps_groups

remove gaps from a binary amino matrix

Description

This function is used to deal with gaps in the binary amino acid encoding. It will remove positions from a binary amino matrix that contain more a certain fraction of gaps for any group in a column, in the alignment. The gap fraction should be between 0 and 1, and can be changed with the gap_fraction variable.

Usage

remove_gaps_groups(x, z, gap_fraction=0.6)

Arguments

x
Matrix representation of alignment generated by convert_aln_amino

z
Vector or factor that shows the group representation for each sequence in the alignment

gap_fraction
Float between 0 and 1 indicating the fraction of gaps in a column before it should be removed

Examples

library(bgafun)
data(LDH)
data(LDH.groups)
LDH.amino=convert_aln_amino(LDH)
dim(LDH.amino)
LDH.amino.gapless=remove_gaps_groups(LDH.amino,LDH.groups,gap_fraction=0.6)
dim(LDH.amino.gapless)

run_between_pca

run PCA to identify functional positions in an alignment

Description

This is a cover function that runs supervised PCA on a matrix that represents an alignment. The matrix can either be a binary matrix (with or without pseudocounts) or one that represents the properties at each position of the alignment.

Usage

run_between_pca(x, z, y)
**Arguments**

- **x**: Matrix representation of alignment generated by convert_aln_amino
- **z**: Matrix representation of alignment generated by convert_aln_amino or convert_aln_AAP
- **y**: Vector or factor that shows the group representation for each sequence in the alignment

**Examples**

```r
library(bgafun)
data(LDH)
data(LDH.groups)
# Used to calculate the sequence weights
data(LDH.amino.gapless)
data(LDH.aap.ave)
# Run the analysis
LDH.aap.ave.bga=run_between_pca(LDH.amino.gapless,LDH.aap.ave,LDH.groups)
class(LDH.aap.ave.bga)
# to visualise the results
plot(LDH.aap.ave.bga)
```

### sum_20_aln

*Calculates number of amino acids in each group of 20 columns (1 column in an alignment)*

**Description**

Internal Function Calculates number of amino acids in each group of 20 columns which corresponds to 1 column in an alignment. It takes in an binary amino acid matrix.

### sum_20_cols

*Calculate number of amino acids in a column of an alignment*

**Description**

Internal Function Sum up 20 columns in an amino acid matrix which corresponds to one column in an alignment.

### sum_aln

*Calculate number of amino acids in each position in an alignment*

**Description**

Internal Function Calculates the total number of amino acids in each position. It is used to identify positions with a high percentage of gaps. It works on an amino acid matrix.
top_residues_2_groups  

Return a list of the top residues at either end of the axis

Description

This will identify the residues that are most discriminating between the two groups, and as such are most likely to be specificity determining residues. It will return a list of the residues at the end of the axis in a bga analysis. It is used when there are two groups. The function create_profile_strings can be used to look at the amino acid content in the column that the analysis identifies.

Usage

top_residues_2_groups(bga_results, residue_number=20)

Arguments

bga_results  
Results of BGA analysis, either from BGA or run_between_pca function

residue_number  
Number of positions at each end of the axis to return

Examples

library(bgafun)
data(LDH.groups)
data(LDH.amino.gapless)
LDH.binary.bga=bga(t(LDH.amino.gapless+1),LDH.groups)
top_res=top_residues_2_groups(LDH.binary.bga)
#To tidy up the results
names(top_res)=sub("X","",names(top_res))
# To look at the amino acid content in the alignment
LDH.profiles=create_profile_strings(LDH.amino.gapless,LDH.groups)
LDH.profiles[, colnames(LDH.profiles) %in% names(top_res)]

Weight_Amino  
Calculates sequence weight for each sequence in an amino acid matrix

Description

Internal Function Calculates sequence weight for each sequence, and multiples the matrix by this weight. It returns a weighted amino acid matrix.
