BS.chr22

Whole-genome bisulfite sequencing for chromosome 22 from Lister et al.

Description

This dataset represents chromosome 22 from the IMR90 cell line sequenced in Lister et al. Only CpG methylation are included (there were very few non-CpG loci). The two samples are two different extractions from the same cell line (ie. technical replicates), and are pooled in the analysis in the original paper.

Usage

data(BS.chr22)

Format

An object of class BSseq.

Details

All coordinates are in hg18.

Source

Obtained from http://neomorph.salk.edu/human_methylome/data.html specifically the files mc_h1_r1.tar.gz and mc_h1_r1.tar.gz. A script which downloads these files and constructs the BS.chr22 object may be found in 'inst/scripts/get_BS.chr22.R', see the example.

References

BSmooth, smoothing bisulfite sequence data

Examples

data(BS.chr22)
BS.chr22

script <- system.file("scripts", "get_BS.chr22.R", package = "bsseq")
script
readLines(script)

Description

This implements the BSmooth smoothing algorithm for bisulfite sequencing data.

Usage

BSmooth(BSseq, ns = 70, h = 1000, maxGap = 10^8,
parallelBy = c("sample", "chromosome"), mc.preschedule = FALSE,
mc.cores = 1, keep.se = FALSE, verbose = TRUE)

Arguments

BSseq  An object of class BSseq.
ns      The minimum number of methylation loci in a smoothing window.
h       The minimum smoothing window, in bases.
maxGap  The maximum gap between two methylation loci, before the smoothing is broken across the gap. The default smoothes each chromosome separately.
parallelBy Should the computation be parallel by chromosome or sample, see details.
mc.preschedule Passed to mclapply (should the tasks be prescheduled).
mc.cores   Passed to mclapply (the number of cores used). Note that setting mc.cores to a value greater than 1 is not supported on MS Windows, see the help page for mclapply.
keep.se    Should the estimated standard errors from the smoothing algorithm be kept. This will make the return object roughly 30 percent bigger and may not be used for anything.
verbose    Should the function be verbose.

Details

ns and h are passed to the locfit function. The bandwidth used is the maximum (in genomic distance) of the h and a width big enough to contain ns number of methylation loci.

The function uses the parallel package to do parallel computations. In order to use this, make sure your system have enough RAM, these are typically big objects. The computation can either be split by chromosome or by sample, which is better depends on the number of samples and how many concurrent smoothings may be done.

Value

An object of class BSseq, containing smoothed values and optionally standard errors for these.
Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

`locfit` in the locfit package, as well as `BSseq`.

Examples

```r
## Not run:
data(BS.chr22)
BS.fit <- BSmooth(BS.chr22, verbose = TRUE)
BS.fit

# An example using a HDF5Array-backed BSseq object
library(HDF5Array)
# See ?SummarizedExperiment::saveHDF5SummarizedExperiment for details
hdf5_BS.chr22 <- saveHDF5SummarizedExperiment(x = BS.chr22,
                                           dir = tempfile())
hdf5_BS.fit <- BSmooth(hdf5_BS.chr22, verbose = TRUE)
hdf5_BS.fit

## End(Not run)
```

BSmooth.tstat

Compute t-statistics based on smoothed whole-genome bisulfite sequencing data.

Description

Compute t-statistics based on smoothed whole-genome bisulfite sequencing data.

Usage

```r
BSmooth.tstat(BSseq, group1, group2,
estimate.var = c("same", "paired", "group2"), local.correct = TRUE,
maxGap = NULL, qSd = 0.75, k = 101, mc.cores = 1, verbose = TRUE)
```

Arguments

- **BSseq**: An object of class BSseq.
- **group1**: A vector of sample names or indexes for the ‘treatment’ group.
- **group2**: A vector of sample names or indexes for the ‘control’ group.
- **estimate.var**: How is the variance estimated, see details.
local.correct A logical; should local correction be used, see details.
maxGap A scalar greater than 0, see details.
qSd A scalar between 0 and 1, see details.
k A positive scalar, see details.
mc.cores The number of cores used. Note that setting mc.cores to a value greater than 1 is not supported on MS Windows, see the help page for mclapply.
verbose Should the function be verbose?

Details
T-statistics are formed as the difference in means between group 1 and group 2 divided by an estimate of the standard deviation, assuming that the variance in the two groups are the same (same), that we have paired samples (paired) or only estimate the variance based on group 2 (group2). The standard deviation estimates are then smoothed (using a running mean with a width of k) and thresholded (using qSd which sets the minimum standard deviation to be the qSd-quantile). Optionally, the t-statistics are corrected for low-frequency patterns.

It is sometimes useful to use local.correct even if no large scale changes in methylation have been found; it makes the marginal distribution of the t-statistics more symmetric.

Additional details in the reference.

Value
An object of class BSseqTstat.

Author(s)
Kasper Daniel Hansen <khansen@jhsph.edu>

References

See Also
BSsmooth for the input object and BSseq for its class. BSseqTstat describes the return class. This function is likely to be followed by the use of dmf
finder. And finally, see the package vignette(s) for more information on how to use it.

Examples
if(require(bsseqData)) {
  data(keepLoci.ex)
  data(BS.cancer.ex.fit)
  BS.cancer.ex.fit <- updateObject(BS.cancer.ex.fit)
  ## Remember to subset the BSseq object, see vignette for explanation
  BS.tstat <- BSmooth.tstat(BS.cancer.ex.fit[keepLoci.ex,],
    group1 = c("C1", "C2", "C3"),
    group2 = c("N1", "N2", "N3"),
    estimate.var = "group2")
  BS.tstat
}
## This object is also stored as BS.cancer.ex.tstat in the bsseqData package

# An example using a HDF5Array-backed BSseq object

```r
library(HDF5Array)
# See ?SummarizedExperiment::saveHDF5SummarizedExperiment for details
hdf5_BS.cancer.ex.fit <- saveHDF5SummarizedExperiment(
  x = BS.cancer.ex.fit[keepLoci.ex, ],
  dir = tempfile())
hdf5_BS.tstat <- BSmooth.tstat(hdf5_BS.cancer.ex.fit, 
  group1 = c("C1", "C2", "C3"),
  group2 = c("N1", "N2", "N3"),
  estimate.var = "group2")
}
```

---

**BSseq**

The constructor function for BSseq objects.

### Description

The constructor function for BSseq objects.

### Usage

```r
BSseq(M = NULL, Cov = NULL, coef = NULL, se.coef = NULL, 
  trans = NULL, parameters = NULL, pData = NULL, gr = NULL, 
  pos = NULL, chr = NULL, sampleNames = NULL, rmZeroCov = FALSE)
```

### Arguments

- **M**  
  A matrix-like object of methylation evidence (see 'Details' below).
- **Cov**  
  A matrix-like object of coverage (see 'Details' below).
- **coef**  
  A matrix-like object of smoothing estimates (see 'Details' below).
- **se.coef**  
  A matrix-like object of smoothing standard errors (see 'Details' below).
- **trans**  
  A smoothing transformation.
- **parameters**  
  A list of smoothing parameters.
- **pData**  
  An data.frame or DataFrame.
- **sampleNames**  
  A vector of sample names.
- **gr**  
  An object of type GRanges.
- **pos**  
  A vector of locations.
- **chr**  
  A vector of chromosomes.
- **rmZeroCov**  
  Should genomic locations with zero coverage in all samples be removed.
Details

The 'M', 'Cov', 'coef', and 'se.coef' matrix-like objects will be coerced to DelayedMatrix objects; see ?DelayedArray::DelayedMatrix for the full list of supported matrix-like objects. We recommend using matrix objects for in-memory storage of data and HDF5Matrix for on-disk storage of data.

Genomic locations are specified either through gr or through chr and pos but not both. There should be the same number of genomic locations as there are rows in the M and Cov matrix.

The argument rmZeroCov may be useful in order to reduce the size of the return object by removing methylation loci with zero coverage.

In case one or more methylation loci appears multiple times, the M and Cov matrices are summed over rows linked to the same methylation loci. See the example below.

Users should never have to specify coef, se.coef, trans, and parameters, this is for internal use (they are added by BSmooth).

phenoData is a way to specify pheno data (as known from the ExpressionSet and eSet classes), at a minimum sampleNames should be given (if they are not present, the function uses col.names(M)).

Value

An object of class BSseq.

                  M = hdf5_M,
                  Cov = hdf5_Cov,
                  sampleNames = c("A", "B", "C"))

hdf5_BS1
BSseq-class

BSseq-class

Class BSseq

Description

A class for representing whole-genome or capture bisulfite sequencing data.

Objects from the Class

An object from the class links together several pieces of information. (1) genomic locations stored as a GRanges object, a location by samples matrix of M values, a location by samples matrix of Cov (coverage) values and phenodata information. In addition, there are slots for representing smoothed data. This class is an extension of RangedSummarizedExperiment.

Slots

trans: Object of class function. This function transforms the coef slot from the scale the smoothing was done to the 0-1 methylation scale.

parameters: Object of class list. A list of parameters representing for example how the data was smoothed.

Methods

[ signature(x = "BSseq"): Subsetting by location (using integer indices) or sample (using integers or sample names).

length Unlike for RangedSummarizedExperiment, length() is the number of methylation loci (equal to length(granges(x))).

sampleNames,sampleNames<- Sample names and its replacement function for the object. This is an alias for colnames.

pData,pData<- Obtain and replace the pData slot of the phenoData slot. This is an alias for colData.

show The show method.

combine This function combines two BSSeq objects. The genomic locations of the new object is the union of the genomic locations of the individual objects. In addition, the methylation data matrices are placed next to each other (as appropriate wrt. the new genomic locations) and zeros are entered into the matrices as needed.
Utilities

This class extends RangedSummarizedExperiment and therefore inherits a number of useful GRanges methods that operate on the rowRanges slot, used for accessing and setting the genomic locations and also do subsetByOverlaps.

There are a number of almost methods-like functions for operating on objects of class BSseq, including getBSseq, collapseBSseq, and orderBSseq. They are detailed below.

collapseBSseq(BSseq, columns) is used to collapse an object of class BSseq. By collapsing we simply mean that certain columns (samples) are merge together by summing up the methylation evidence and coverage. This is a useful function if you start by reading in a dataset based on say flowcells and you (after QC) want to simply add a number of flowcells into one sample. The argument columns specify which samples are to be merged, in the following way: it is a character vector of new sample names, and the names of the column vector indicates which samples in the BSseq object are to be collapsed. If columns have the same length as the number of rows of BSseq (and has no names) it is assumed that the ordering corresponds to the sample ordering in BSseq.

orderBSseq(BSseq, seqOrder = NULL) simply orders an object of class BSseq according to (increasing) genomic locations. The seqOrder vector is a character vector of seqnames(BSseq) describing the order of the chromosomes. This is useful for ordering chr1 before chr10.

chrSelectBSseq(BSseq, seqnames = NULL, order = FALSE) subsets and optionally reorders an object of class BSseq. The seqnames vector is a character vector of seqnames(BSseq) describing which chromosomes should be retained. If order is TRUE, the chromosomes are also re-ordered using orderBSseq.

getBSseq(BSseq, type = c("Cov", "M", "gr", "coef", "se.coef", "trans", "parameters")) is a general accessor: is used to obtain a specific slot of an object of class BSseq. It is primarily intended for internal use in the package, for users we recommend granges to get the genomic locations, getCoverage to get the coverage slots and getMeth to get the smoothed values (if they exist).

hasBeenSmoothed(BSseq) This function returns a logical depending on whether or not the BSseq object has been smoothed using BSmooth.

combineList(list, BACKEND = NULL) This function function is a faster way of using combine on multiple BSseq objects. The input is a list, with each component an object of class BSseq. The (slower) alternative is to use Reduce(combine, list).

The BACKEND argument determines which backend should be used for the 'M' and 'Cov' matrices and, if present, the 'coef' and 'se.coef' matrices (the latter two can only be combined if all objects have the same rowRanges). The default, BACKEND = NULL, corresponds to using matrix objects. See ?DelayedArray::setRealizationBackend for alternative backends.

strandCollapse(BSseq, shift = TRUE) This function operates on a BSseq objects which has stranded loci (ie. loci where the strand is one of '+’ or ‘-’). It will collapse the methylation and coverage information across the two strands, into one position. The argument shift indicates whether the positions for the loci on the reverse strand should be shifted one (ie. the positions for these loci are the positions of the ‘G’ in the ‘CpG’; this is the case for Bismark output for example.

Coercion

Package versions 1.5.2 and 1.11.1 introduced a new version of representing ‘BSseq’ objects. You can update old serialized (saved) objects by invoking x <- updateObject(x).
BSseqStat-class

Assays

This class overrides the default implementation of assays to make it faster. Per default, no names are added to the returned data matrices.

Assay names can conveniently be obtained by the function assayNames(x)

The package vignette. BSseq for the constructor function. RangedSummarizedExperiment for the underlying class. getBSseq, getCoverage, and getMeth for accessing the data stored in the object and finally BSmooth for smoothing the bisulfite sequence data.

Examples

M <- matrix(1:9, 3,3)
colnames(M) <- c("A1", "A2", "A3")
BStest <- BSseq(pos = 1:3, chr = c("chr1", "chr2", "chr1"), M = M, Cov = M + 2)
chrSelectBSseq(BStest, seqnames = "chr1", order = TRUE)
collapseBSseq(BStest, columns = c("A1" = "A", "A2" = "A", "A3" = "B"))

# An example using a HDF5-backed BSseq object
# library(HDF5Array)
# See ?HDF5Array::writeHDF5Array for details
hdf5_M <- writeHDF5Array(M)
# NOTE: HDF5Array::writeHDF5Array() doesn't preserve dimnames, so have to add
# these manually
dimnames(hdf5_M) <- dimnames(M)
hdf5_BStest <- BSseq(pos = 1:3,
                          chr = c("chr1", "chr2", "chr1"),
                          M = hdf5_M,
                          Cov = hdf5_M + 2)
chrSelectBSseq(hdf5_BStest, seqnames = "chr1", order = TRUE)
collapseBSseq(hdf5_BStest, columns = c("A1" = "A", "A2" = "A", "A3" = "B"))

BSseqStat-class

Class BSseqStat

Description

A class for representing statistics for smoothed whole-genome bisulfite sequencing data.

Usage

BSseqStat(gr = NULL, stats = NULL, parameters = NULL)
**BSseqStat-class**

**Arguments**

- **gr** The genomic locations as an object of class GRanges.
- **stats** The statistics, as a list of matrix-like objects (see 'Details' below).
- **parameters** A list of parameters.

**Details**

The matrix-like elements of the list in the 'stats' slot will be coerced to DelayedMatrix objects; see ?DelayedArray::DelayedMatrix for the full list of supported matrix-like objects. We recommend using matrix objects for in-memory storage of data and HDF5Matrix for on-disk storage of data.

**Objects from the Class**

Objects can be created by calls of the form BSseqStat(...). However, usually objects are returned by BSmooth.fstat(...) and not constructed by the user.

**Slots**

- **stats**: This is a list of DelayedMatrix objects with list elements representing various statistics for methylation loci along the genome.
- **parameters**: Object of class list. A list of parameters representing how the statistics were computed.
- **gr**: Object of class GRanges giving genomic locations.

**Extends**

Class hasGRanges, directly.

**Methods**

- [ The subsetting operator; one may only subset in one dimension, corresponding to methylation loci.
- **show** The show method.

**Utilities**

This class extends hasGRanges and therefore inherits a number of useful GRanges methods that operate on the gr slot, used for accessing and setting the genomic locations and also dosubsetByOverlaps.

**Coercion**

Package version 1.11.1 introduced a new version of representing 'BSseqStat' objects. You can update old serialized (saved) objects by invoking x <- updateObject(x).

**Author(s)**

Kasper Daniel Hansen <khansen@jhsph.edu>

**See Also**

hasGRanges for accessing the genomic locations. BSmooth.fstat for a function that returns objects of class BSseqStat, and smoothSds, computeStat and dmrFinder for functions that operate based on these statistics. Also see the more specialised BSseqTstat.
BSseqTstat-class

Class BSseqTstat

Description
A class for representing t-statistics for smoothed whole-genome bisulfite sequencing data.

Usage
BSseqTstat(gr = NULL, stats = NULL, parameters = NULL)

Arguments
- gr: The genomic locations as an object of class GRanges.
- stats: The statistics, as a matrix-like object (see ‘Details’ below).
- parameters: A list of parameters.

Details
The ‘stats’ matrix-like object will be coerced to a DelayedMatrix object; see ?DelayedArray::DelayedMatrix for the full list of supported matrix-like objects. We recommend using matrix objects for in-memory storage of data and HDF5Matrix for on-disk storage of data.

Objects from the Class
Objects can be created by calls of the form BSseqTstat(...). However, usually objects are returned by BSmooth.tstat(...) and not constructed by the user.

Slots
- stats: This is a DelayedMatrix object with columns representing various statistics for methylation loci along the genome.
- parameters: Object of class list. A list of parameters representing how the t-statistics were computed.
- gr: Object of class GRanges giving genomic locations.

Extends
Class hasGRanges, directly.

Methods
- \[\]: The subsetting operator; one may only subset in one dimension, corresponding to methylation loci.
- show: The show method.

Utilities
This class extends hasGRanges and therefore inherits a number of useful GRanges methods that operate on the gr slot, used for accessing and setting the genomic locations and also do subsetByOverlaps.
Coercion

Package version 1.11.1 introduced a new version of representing 'BSseqTstat' objects. You can update old serialized (saved) objects by invoking `x <- updateObject(x)`.

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

See Also

The package vignette(s), `hasGRanges` for accessing the genomic locations, `BSmooth.tstat` for a function that returns objects of class `BSseqTstat`, and `dmrFinder` for a function that computes DMRs based on the t-statistics. Also see `BS.cancer.ex.tstat` for an example of the class in the `bsseqData` package.

data.frame2GRanges (df, keepColumns = FALSE, ignoreStrand = FALSE)

Description

Converting a data.frame to a GRanges object. The data.frame needs columns like chr, start and end (strand is optional). Additional columns may be kept in the GRanges object.

Usage

data.frame2GRanges(df, keepColumns = FALSE, ignoreStrand = FALSE)

Arguments

df

A data.frame with columns chr or seqnames, start, end and optionally a strand column.

keepColumns

In case df has additional columns, should these columns be stored as metadata columns on the return GRanges or should they be discarded.

ignoreStrand

In case df has a strand column, should this column be ignored.

Value

An object of class GRanges

Note

In case df has rownames, they will be used as names for the return object.

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

Examples

df <- data.frame(chr = "chr1", start = 1:3, end = 2:4, 
                  strand = c("+","-","+"))

data.frame2GRanges(df, ignoreStrand = TRUE)
**dmrFinder**

Finds differentially methylated regions for whole genome bisulfite sequencing data.

**Description**

Finds differentially methylated regions for whole genome bisulfite sequencing data. Essentially identifies regions of the genome where all methylation loci have an associated t-statistic that is beyond a (low, high) cutoff.

**Usage**

```r
dmrFinder(bstat, cutoff = NULL, qcutoff = c(0.025, 0.975),
          maxGap=300, stat = "tstat.corrected", verbose = TRUE)
```

**Arguments**

- `bstat`: An object of class `BSseqStat` or `BSseqTstat`.
- `cutoff`: The cutoff of the t-statistics. This should be a vector of length two giving the (low, high) cutoff. If NULL, see `qcutoff`.
- `qcutoff`: In case cutoff is NULL, compute the cutoff using these quantiles of the t-statistic.
- `maxGap`: If two methylation loci are separated by this distance, break a possible DMR. This guarantees that the return DMRs have CpGs that are this distance from each other.
- `stat`: Which statistic should be used?
- `verbose`: Should the function be verbose?

**Details**

The workhorse function is `BSmooth.tstat` which sets up a t-statistic for a comparison between two groups.

Note that post-processing of these DMRs are likely to be necessary, filtering for example for length (or number of loci).

**Value**

A data.frame with columns

- `start`, `end`, `width`, `chr` genomic locations and width.
- `n` The number of methylation loci.
- `invdensity` Average length per loci.
- `group1.mean` The mean methylation level across samples and loci in 'group1'.
- `group2.mean` The mean methylation level across samples and loci in 'group2'.
- `meanDiff` The mean difference in methylation level; the difference between `group1.mean` and `group2.mean`.
- `idxStart`, `idxEnd`, `cluster` Internal use.
areaStat: The 'area' of the t-statistic; equal to the sum of the t-statistics for the individual methylation loci.
direction: either 'hyper' or 'hypo'.
areaStat.corrected: Only present if column = "tstat.corrected", contains the area of the corrected t-statistics.

Author(s)
Kasper Daniel Hansen <khansen@jhsph.edu>

References

See Also
BSmooth.tstat for the function constructing the input object, and BSseqTstat for its class. In the example below, we use BS.cancer.ex.tstat as the actual input object. Also see the package vignette(s) for a detailed example.

Examples
```r
if(require(bsseqData)) {
  dmrs0 <- dmrFinder(BS.cancer.ex.tstat, cutoff = c(-4.6, 4.6), verbose = TRUE)
  dmrs <- subset(dmrs0, abs(meanDiff) > 0.1 & n >= 3)
}
```

`fisherTests`  
Compute Fisher-tests for a BSseq object

Description
A function to compute Fisher-tests for an object of class BSseq.

Usage
```r
fisherTests(BSseq, group1, group2, lookup = NULL,
            returnLookup = TRUE, mc.cores = 1, verbose = TRUE)
```

Arguments
- `BSseq`: An object of class BSseq.
- `group1`: A vector of sample names or indexes for the 'treatment' group.
- `group2`: A vector of sample names or indexes for the 'control' group.
- `lookup`: A 'lookup' object, see details.
- `returnLookup`: Should a 'lookup' object be returned, see details.
- `mc.cores`: The number of cores used. Note that setting mc.cores to a value greater than 1 is not supported on MS Windows, see the help page for mclapply.
- `verbose`: Should the function be verbose.
Details

This function computes row-wise Fisher’s exact tests. It uses an internal lookup table so rows which forms equivalent 2x2 tables are group together and only a single test is computed. If returnLookup is TRUE the return object contains the lookup table which may be feed to another call to the function using the lookup argument.

If group1, group2 designates more than 1 sample, the samples are added together before testing.

This function can use multiple cores on the same computer.

This test cannot model biological variability.

Value

if returnLookup is TRUE, a list with components results and lookup, otherwise just the results component. The results (component) is a matrix with the same number of rows as the BSseq argument and 2 columns p.value (the unadjusted p-values) and log2OR (log2 transformation of the odds ratio).

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

See Also

fisher.test for information about Fisher’s test. mclapply for the mc.cores argument.

Examples

```R
M <- matrix(1:9, 3,3)
colnames(M) <- c("A1", "A2", "A3")
BStest <- BSseq(pos = 1:3, chr = c("chr1", "chr2", "chr1"),
    M = M, Cov = M + 2)
results <- fisherTests(BStest, group1 = "A1", group2 = "A2",
    returnLookup = TRUE)
results

# An example using a HDF5Array-backed BSseq object
#
library(HDF5Array)
# See ?SummarizedExperiment::saveHDF5SummarizedExperiment for details
hdf5_BStest <- saveHDF5SummarizedExperiment(x = BStest, dir = tempfile())
results <- fisherTests(hdf5_BStest, group1 = "A1",
    group2 = "A2",
    returnLookup = TRUE)
results
```
**getCoverage**

**Obtain coverage for BSseq objects.**

**Description**

Obtain coverage for BSseq objects.

**Usage**

```r
getCoverage(BSseq, regions = NULL, type = c("Cov", "M"),
            what = c("perBase", "perRegionAverage", "perRegionTotal"))
```

**Arguments**

- **BSseq**: An object of class BSseq.
- **regions**: An optional data.frame or GenomicRanges object specifying a number of genomic regions.
- **type**: This returns either coverage or the total evidence for methylation at the loci.
- **what**: The type of return object, see details.

**Value**

**NOTE:** The return type of getCoverage varies depending on its arguments.

- If `regions` are not specified (`regions = NULL`) a DelayedMatrix object (`what = "perBase"`) is returned. This will either contain the per-base coverage, the average coverage, or the genome total coverage (depending on value of `what`).

- If `what = "perBase"` and `regions` are specified, a list is returned. Each element of the list is a DelayedMatrix object corresponding to the genomic loci inside the region. It is conceptually the same as splitting the coverage by region.

- If `what = "perRegionAverage"` or `what = "perRegionTotal"` and `regions` are specified the return value is a DelayedMatrix object. Each row of the DelayedMatrix corresponds to a region and contains either the average coverage or the total coverage in the region.

**Author(s)**

Kasper Daniel Hansen <khansen@jhsph.edu>.

**See Also**

**Examples**

```r
data(BS.chr22)
head(getCoverage(BS.chr22, type = "M"))
reg <- GRanges(seqnames = c("chr22", "chr22"),
              ranges = IRanges(start = c(1, 2*10^7), end = c(2*10^7 +1, 4*10^7)))
getCoverage(BS.chr22, regions = reg, what = "perRegionAverage")
cList <- getCoverage(BS.chr22, regions = reg)
length(cList)
head(cList[[1]])
```
# An example using a HDF5Array-backed BSseq object
#

library(HDF5Array)
# See ?SummarizedExperiment::saveHDF5SummarizedExperiment for details
hdf5_BS.chr22 <- saveHDF5SummarizedExperiment(x = BS.chr22, dir = tempfile())
head(getCoverage(hdf5_BS.chr22, type = "M"))
reg <- GRanges(seqnames = c("chr22", "chr22"),
  ranges = IRanges(start = c(1, 2 * 10^7),
                   end = c(2 * 10^7 + 1, 4 * 10^7)))
getCoverage(hdf5_BS.chr22, regions = reg, what = "perRegionAverage")
hdf5_cList <- getCoverage(hdf5_BS.chr22, regions = reg)
length(hdf5_cList)
head(hdf5_cList[[1]])

---

goMeth

Obtain methylation estimates for BSseq objects.

**Description**

Obtain methylation estimates for BSseq objects, both smoothed and raw.

**Usage**

```r
getMeth(BSseq, regions = NULL, type = c("smooth", "raw"),
  what = c("perBase", "perRegion"), confint = FALSE, alpha = 0.95)
```

**Arguments**

- **BSseq**
  - An object of class BSseq.
- **regions**
  - An optional data.frame or GenomicRanges object specifying a number of genomic regions.
- **type**
  - This returns either smoothed or raw estimates of the methylation level.
- **what**
  - The type of return object, see details.
- **confint**
  - Should a confidence interval be return for the methylation estimates (see below). This is only supported if what is equal to perBase.
- **alpha**
  - alpha value for the confidence interval.

**Value**

**NOTE:** The return type of `getMeth` varies depending on its arguments.

If `region = NULL` the what argument is ignored. This is also the only situation in which `confint = TRUE` is supported. The return value is either a `DelayedMatrix` (`confint = FALSE` or a list with three `DelayedMatrix` components `confint = TRUE` (meth, upper and lower), giving the methylation estimates and (optionally) confidence intervals.

Confidence intervals for `type = "smooth"` is based on standard errors from the smoothing algorithm (if present). Otherwise it is based on pointwise confidence intervals for binomial distributions described in Agresti (see below), specifically the score confidence interval.
If regions are specified, what = "perBase" will make the function return a list, each element of the list being a DelayedMatrix corresponding to a genomic region (and each row of the DelayedMatrix being a loci inside the region). If what = "perRegion" the function returns a DelayedMatrix, with each row corresponding to a region and containing the average methylation level in that region.

**Note**

A BSseq object needs to be smoothed by the function BSmooth in order to support type = "smooth".

**Author(s)**

Kasper Daniel Hansen <khansen@jhsph.edu>.

**References**

**See Also**

BSseq for the BSseq class and BSmooth for smoothing such an object.

**Examples**

data(BS.chr22)
head(getMeth(BS.chr22, type = "raw"))
reg <- GRanges(seqnames = c("chr22", "chr22"),
    ranges = IRanges(start = c(1, 2*10^7), end = c(2*10^7 +1, 4*10^7)))
head(getMeth(BS.chr22, regions = reg, type = "raw", what = "perBase"))

# An example using a HDF5Array-backed BSseq object
#
library(HDF5Array)
# See ?SummarizedExperiment::saveHDF5SummarizedExperiment for details
hdf5_BS.chr22 <- saveHDF5SummarizedExperiment(x = BS.chr22,
    dir = tempfile())
head(getMeth(hdf5_BS.chr22, type = "raw"))
head(getMeth(hdf5_BS.chr22, regions = reg, type = "raw", what = "perBase"))

---

### getStats

Obtain statistics from a BSseqTstat object

**Description**

Essentially an accessor function for the statistics of a BSseqTstat object.

**Usage**

getStats(bstat, regions = NULL, ...)
GoodnessOfFit

Arguments

bstat  An object of class BSseqStat or BSseqTstat.
regions  An optional data.frame or GenomicRanges object specifying a number of genomic regions.
...  Additional arguments passed to the different backends based on the class of bstat; see Details.

Details

Additional argument when the bstat object is of class BSseqTstat:

stat  Which statistics column should be obtained.

Value

An object of class data.frame possible restricted to the regions specified.

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

See Also

BSseqTstat for the BSseqTstat class, and getCoverage and getMeth for similar functions, operating on objects of class BSseq.

Examples

if(require(bsseqData)) {
  data(BS.cancer.ex.tstat)
  head(getStats(BS.cancer.ex.tstat))
  reg <- GRanges(seqnames = c("chr22", "chr22"),
                 ranges = IRanges(start = c(1, 2*10^7), end = c(2*10^7 +1, 4*10^7)))
  head(getStats(BS.cancer.ex.tstat, regions = reg))
}

GoodnessOfFit  Binomial and poisson goodness of fit statistics for BSSeq objects

Description

Binomial and poisson goodness of fit statistics for BSSeq objects, including plotting capability.

Usage

poissonGoodnessOfFit(BSseq, nQuantiles = 10^5)
binomialGoodnessOfFit(BSseq, method = c("MLE"), nQuantiles = 10^5)
## S3 method for class 'chisqGoodnessOfFit'
print(x, ...)  ## S3 method for class 'chisqGoodnessOfFit'
plot(x, type = c("chisq", "pvalue"), plotCol = TRUE, qqline = TRUE,
      pch = 16, cex = 0.75, ...)
GoodnessOfFit

Arguments

BSseq An object of class BSseq.
x A chisqGoodnessOfFit object (as produced by poissonGoodnessOfFit or binomialGoodnessOfFit).
nQuantiles The number of (evenly-spaced) quantiles stored in the return object.
method How is the parameter estimated.
type Are the chisq or the p-values being plotted.
plotCol Should the extreme quantiles be colored.
qqline Add a qqline.
pch, cex Plotting symbols and size.
... Additional arguments being passed to qqplot (for plot) or ignored (for print).

Details

These functions compute and plot goodness of fit statistics for BSseq objects. For each methylation loci, the Poisson goodness of fit statistic tests whether the coverage (at that loci) is independent and identically Poisson distributed across the samples. In a similar fashion, the Binomial goodness of fit statistic tests whether the number of reads supporting methylation are independent and identically binomial distributed across samples (with different size parameters given by the coverage vector).

These functions do not handle NA values.

Value

The plotting method is invoked for its side effect. Both poissonGoodnessOfFit and binomialGoodnessOfFit returns an object of class chisqGoodnessOfFit which is a list with components

chisq a vector of Chisq values.
quantiles a vector of quantiles (of the chisq values).
df degrees of freedom

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

See Also

For the plotting method, see qqplot.

Examples

if(require(bsseqData)) {
  data(BS.cancer.ex)
  BS.cancer.ex <- updateObject(BS.cancer.ex)
  gof <- poissonGoodnessOfFit(BS.cancer.ex)
  plot(gof)

  # An example using a HDF5Array-backed BSseq object

  library(HDF5Array)
hasGRanges-class

Description

A class with a GRanges slot, used as a building block for other classes. Provides basic accessor functions etc.

Objects from the Class

Objects can be created by calls of the form new("hasGRanges", ...).

Slots

gr: Object of class GRanges.

Methods

"[" Subsets a single dimension.

granges Get the GRanges object representing genomic locations.

start,start<-,end,end<-,width,width<- Start, end and width for the genomic locations of the object, also replacement functions. This accessor functions operate directly on the gr slot.

strand,strand<- Getting and setting the strand of the genomic locations (the gr slot).

seqlengths,seqlengths<- Getting and setting the seqlengths of the genomic locations (the gr slot).

seqlevels,seqlevels<- Getting and setting the seqlevels of the genomic locations (the gr slot).

seqnames,seqnames<- Getting and setting the seqnames of the genomic locations (the gr slot).

show The show method.

findOverlaps (query = "hasGRanges", subject = "hasGRanges"): finds overlaps between the granges() of the two objects.

findOverlaps (query = "GenomicRanges", subject = "hasGRanges"): finds overlaps between query and the granges() of the subject.

findOverlaps (query = "hasGRanges", subject = "GenomicRanges"): finds overlaps between the granges() of the query and the subject.

subsetByOverlaps (query = "hasGRanges", subject = "hasGRanges"): Subset the query, keeping the genomic locations that overlaps the subject.

subsetByOverlaps (query = "GenomicRanges", subject = "hasGRanges"): Subset the query, keeping the genomic locations that overlaps the subject.

subsetByOverlaps (query = "GenomicRanges", subject = "hasGRanges"): Subset the query, keeping the genomic locations that overlaps the subject.
Plotting BSmooth methylation estimates

**Description**

Functions for plotting BSmooth methylation estimates. Typically used to display differentially methylated regions.

**Usage**

```r
plotRegion(BSseq, region = NULL, extend = 0, main = "", 
  addRegions = NULL, annoTrack = NULL, cex.anno = 1, 
  geneTrack = NULL, cex.gene = 1.5, col = NULL, lty = NULL, 
  lwd = NULL, BSseqStat = NULL, stat = "tstat.corrected", 
  stat.col = "black", stat.lwd = 1, stat.lty = 1, stat ylim = c(-8, 8), 
  mainWithWidth = TRUE, regionCol = alpha("red", 0.1), addTicks = TRUE, 
  addPoints = FALSE, pointsMinCov = 5, highlightMain = FALSE)
```

```r
plotManyRegions(BSseq, regions = NULL, extend = 0, main = "", 
  addRegions = NULL, annoTrack = NULL, cex.anno = 1, 
  geneTrack = NULL, cex.gene = 1.5, col = NULL, lty = NULL, 
  lwd = NULL, BSseqStat = NULL, stat = "tstat.corrected", 
  stat.col = "black", stat.lwd = 1, stat.lty = 1, stat ylim = c(-8, 8), 
  mainWithWidth = TRUE, regionCol = alpha("red", 0.1), addTicks = TRUE, 
  addPoints = FALSE, pointsMinCov = 5, highlightMain = FALSE, 
  verbose = TRUE)
```

**Arguments**

- **BSseq**
  An object of class BSseq.

- **region**
  A `data.frame` (with start, end and chr columns) with 1 row or GRanges of length 1. If region is `NULL` the entire BSseq argument is plotted.

- **regions**
  A `data.frame` (with start, end and chr columns) or GRanges.

- **extend**
  Describes how much the plotting region should be extended in either direction. The total width of the plot is equal to the width of the region plus twice extend.

- **main**
  The plot title. The default is to construct a title with information about which genomic region is being plotted.
addRegions  A set of additional regions to be highlighted on the plots. As the regions argument.
annoTrack  A named list of GRanges objects. Each component is a track and the names of the list are the track names. Each track will be plotted as solid bars, and we routinely display information such as CpG islands, exons, etc.
cex.anno  cex argument when plotting annoTrack.
geneTrack  EXPERIMENTAL: A data.frame with columns: chr, start, end, gene_ID, exon_number, strand, gene_name, isoforms. This interface is under active development and subject to change.
cex.gene  cex argument when plotting geneTrack.
col  The color of the methylation estimates, see details.
lty  The line type of the methylation estimates, see details.
lwd  The line width of the methylation estimates, see details.
BSseqStat  An object of class BSseqStat. If present, a new panel will be shown with the t-statistics.
stat  Which statistics will be plotted (only used if BSseqStat is not NULL.)
stat.col  color for the statistics plot.
stat.lwd  line width for the statistics plot.
stat.lty  line type for the statistics plot.
stat.ylim  y-limits for the statistics plot.
mainWithWidth  Should the default title include information about width of the plot region.
regionCol  The color used for highlighting the region.
addTicks  Should tick marks showing the location of methylation loci, be added?
addPoints  Should the individual unsmoothed methylation estimates be plotted. This usually leads to a very confusing plot, but may be useful for diagnostic purposes.
pointsMinCov  The minimum coverage a methylation loci need in order for the raw methylation estimates to be plotted. Useful for filtering out low coverage loci. Only used if addPoints = TRUE.
highlightMain  Should the plot region be highlighted?
verbose  Should the function be verbose?

Details
The correct choice of aspect ratio depends on the width of the plotting region. We tend to use width = 10, height = 5.
plotManyRegions is used to plot many regions (hundreds or thousands), and is substantially quicker than repeated calls to plotRegion.
This function has grown to be rather complicated over time. For custom plotting, it is sometimes useful to use the function definition as a skeleton and directly modify the code.

Value
This function is invoked for its side effect: producing a plot.

Author(s)
Kasper Daniel Hansen <khansen@jhsph.edu>
read.bismark

Parsing output from the Bismark alignment suite.

Description

Parsing output from the Bismark alignment suite.

Usage

read.bismark(files, sampleNames, rmZeroCov = FALSE, strandCollapse = TRUE, fileType = c("cov", "oldBedGraph", "cytosineReport"), mc.cores = 1, verbose = TRUE, BACKEND = NULL)

Arguments

files Input files. Each sample is in a different file. Input files are created by running Bismark’s methylation extractor; see Note for details.
sampleNames sample names, based on the order of files.
rmZeroCov Should methylation loci that have zero coverage in all samples be removed. This will result in a much smaller object if the data originates from (targeted) capture bisulfite sequencing.
strandCollapse Should strand-symmetric methylation loci, e.g., CpGs, be collapsed across strands. This option is only available if fileType = "cytosineReport" since the other file types do not contain the necessary strand information.
fileType The format of the input file; see Note for details.
mc.cores The number of cores used. Note that setting mc.cores to a value greater than 1 is not supported on MS Windows, see the help page for mclapply.
verbose Make the function verbose.
BACKEND The backend used for the 'M' and 'Cov' matrices. The default, NULL, corresponds to using matrix objects. See ?DelayedArray::setRealizationBackend for alternative backends.

Value

An object of class BSseq.
Note

Input files can either be gzipped or not.

The user must specify the relevant file format via the fileType argument. The format of the output of the Bismark alignment suite will depend on the version of Bismark and on various user-specified options. Please consult the Bismark documentation and the Bismark RELEASE NOTES (http://www.bioinformatics.bbsrc.ac.uk/projects/bismark/RELEASE_NOTES.txt) for the definitive list of changes between versions. When possible, it is strongly recommended that you use the most recent version of Bismark.

The "cov" and "oldBedGraph" formats both have six columns ("chromosome", "position", "strand", "methylation percentage", "count methylated", "count unmethylated"). If you are using a recent version of Bismark (v>=0.10.0) then the standard file extension for this file is "cov". If, however, you are using an older version of Bismark (v<0.10.0) then the file extension will be "bedGraph". Please note that the "bedGraph" file created in recent versions of Bismark (v>=0.10.0) is not suitable for analysis with bsseq because it only contains the "methylation percentage" and not "count methylated" nor "count unmethylated".

The "cytosineReport" format has seven columns ("chromosome", "position", "strand", "count methylated", "count unmethylated", "C-context", "trinucleotide context"). There is no standard file extension for this file. The "C-context" and "trinucleotide context" columns are not currently used by bsseq.

The following is a list of some issues to be aware of when using output from Bismark's methylation extractor:

- The program to extract methylation counts was named methylisation_extractor in older versions of Bismark (v<0.8.0) and re-named bismark_methylisation_extractor in recent versions of Bismark (v>=0.8.0). Furthermore, very old versions of Bismark (v<0.7.7) required that user run a separate script (called something like genome_methylisation_bismark2bedGraph) to create the six-column "cov"/"oldBedGraph" file.
- The --counts and --bedGraph arguments must be supplied to methylisation_extractor/bismark_methylisation_extractor in order to use the output with bsseq::read.bismark().
- The genomic co-ordinates of the Bismark output file may be zero-based or one-based depending on whether the --zero_based argument is used. Furthermore, the default co-ordinate system varies by version of Bismark. bsseq makes no assumptions about the basis of the genomic co-ordinates and it is left to the user to ensure that the appropriate basis is used in the analysis of their data. Since Bioconductor packages and GRanges use one-based co-ordinates, it is recommended that your Bismark files are also one-based.

Peter Hickey <peter.hickey@gmail.com>

See Also

read.bsmooth for parsing output from the BSmooth alignment suite. read.umtab for parsing legacy (old) formats from the BSmooth alignment suite. collapseBSseq for collapse (merging or summing) the data in two different directories.

Examples

```r
infile <- system.file("extdata/test_data.fastq_bismark.bismark.cov.gz", package = 'bsseq')
bismarkBSseq <- read.bismark(files = infile,
```
read.bsmooth

Parsing output from the BSmooth alignment suite

Description

Parsing output from the BSmooth alignment suite.

Usage

read.bsmooth(dirs, sampleNames = NULL, seqnames = NULL, returnRaw = FALSE, qualityCutoff = 20, rmZeroCov = FALSE, verbose = TRUE)

Arguments

dirs        Input directories. Usually each sample is in a different directory, or perhaps each (sample, lane) is a different directory.
sampleNames sample names, based on the order of dirs. If NULL either set to basename(dirs) (if unique) or dirs.
seqnames    The default is to read all BSmooth output files in dirs. Using this argument, it is possible to restrict this to only files with names in seqnames (apart from .cpg.tsv and optionally .gz).
returnRaw   Should the function return the complete information in the output files?
qualityCutoff Only use evidence (methylated and unmethylated evidence) for a given methylation loci, if the base in the read has a quality greater than this cutoff.
rmZeroCov   Should methylation loci that have zero coverage in all samples be removed. This will result in a much smaller object if the data originates from (targeted) capture bisulfite sequencing.
verbose     Make the function verbose.
Value

Either an object of class BSseq (if returnRaw = FALSE) or a list of GRanges which each component coming from a directory.

Note

Input files can either be gzipped or not. Gzipping the input files results in much greater speed of reading (and saves space), so it is recommended.

We are working on making this function faster and less memory hungry.

Author(s)

Kasper Daniel Hansen <khansen@jhsph.edu>

See Also

read.umtab for parsing legacy (old) formats from the BSmooth alignment suite. collapseBSseq for collapse (merging or summing) the data in two different directories.

read.umtab Parsing UM tab files (legacy output) containing output from the BSmooth aligner.

Description

Parsing UM tab files containing output from the bisulfite aligner Merman. This is two different legacy formats, which we keep around. These functions are likely to be deprecated in the future.

Usage

read.umtab(dirs, sampleNames = NULL, rmZeroCov = FALSE,
  pattern = NULL, keepU = c("U10", "U20", "U30", "U40"),
  keepM = c("M10", "M20", "M30", "M40"), verbose = TRUE)

read.umtab2(dirs, sampleNames = NULL, rmZeroCov = FALSE,
  readCycle = FALSE, keepFilt = FALSE,
  pattern = NULL, keepU, keepM, verbose = TRUE)

Arguments

dirs Input directories. Usually each sample is in a different directory.

pattern An optional pattern, see list.files in the base package.
sampleNames sample names, based on the order of dirs.

rmZeroCov Should methylation loci that have zero coverage in all samples be removed. This will result in a much smaller object if the data originates from (targeted) capture bisulfite sequencing.

keepU A vector of U columns which are kept.

keepM A vector of M columns which are kept.

readCycle Should the cycle columns be returned?

keepFilt Should the filter columns be returned?

verbose Make the function verbose.
Details

`read.umtab2` is newer than `read.umtab` and both process output from older versions of the BSmooth alignment suite (versions older than 0.6.1). These functions are likely to be deprecated in the future. Newer output from the BSmooth alignment suite can be parsed using `read.bsmooth`.

A script using this function can be found in the `bsseqData` package, in the file `scripts/create_BS.cancer.R`.

Value

Both functions returns lists, the components are

- **BSdata**: An object of class BSseq containing the methylation evidence.
- **GC**: A vector of local GC content values.
- **Map**: A vector of local mapability values.
- **Mcy**: A matrix of the number of unique M cycles.
- **Ucy**: A matrix of the number of unique U cycles.
- **chr**: A vector of chromosome names.
- **pos**: A vector of genomic positions.
- **M**: A matrix representing methylation evidence.
- **U**: A matrix representing un-methylation evidence.
- **csums**: Description of `comp2`
