- `$dmat3`: num [1:146, 1:146] 0 0.763 1.25 8.571 11.233 ...
  - attr(*, "dimnames")=List of 2
  - ...$ : chr [1:146] "200" "201" "202" "203" ...
  - ...$ : chr [1:146] "200" "201" "202" "203" ...

- `$taxa`: Factor w/ 33 levels "Actinomyces bowdenii",...
  - 12 12 12 23 20 8 22 12 20 ...

- `$abbrev`: Factor w/ 33 levels "A bowdenii", "A canis",...
  - 12 12 12 23 20 8 22 12 20 ...

**Details**

The matrices `$dmat1`, `$dmat2`, and `$dmat3` contain percent nucleotide difference with indels penalized heavily, little, and somewhat, respectively.

$taxa$ is a factor of species names; abbreviations of the same names are found in `$abbrev$`.

**Examples**

data(actino)

---

**bvseqs**

*BV reference set.*

**Description**

Tree-derived pairwise distances and taxonomic assignments among 16S rRNA sequences representing bacteria represented in the vaginal mucosa.

**Usage**

data(bvseqs)
Format

The format is:

classify

Description

Functions to perform classification by local similarity threshold.
classify

Usage

classify(dmat, groups, dvect, method = "mutinfo", minScore = 0.45,
         doffset = 0.5, dStart = NA, maxDepth = 10, minGroupSize = 2,
         objNames = names(dvect), keep.data = TRUE, ..., verbose = FALSE)
classifyIter(dmat, groupTab, dvect, dStart = NA, multiple = FALSE,
              keep.data = TRUE, ..., verbose = FALSE)
classifier(dmat, groups, dvect, method = 'mutinfo', minScore = 0.45,
           doffset = 0.5, dStart = NA, minGroupSize = 2,
           objNames = names(dvect), keep.data = TRUE, ..., verbose = FALSE,
           depth = 1)
pull(dmat, groups, index)
pullTab(dmat, groupTab, index)

Arguments

dmat          Square matrix of pairwise distances.
groups        Object coercible to a factor identifying group membership of objects corresponding to either edge of dmat.
groupTab      a data.frame representing a taxonomy, with columns in increasing order of specificity from left to right (i.e., Kingdom -> Species). Column names are used to name taxonomic ranks. Rows correspond to margins of dmat.
dvect         numeric vector of distance from query sequence to each reference corresponding to margins of dmat.
method        The method for calculating the threshold; only 'mutinfo' is currently implemented.
minScore      Threshold value for the match score to define a match.
doffset       Offset used in the denominator of the expression to calculate match score to penalize very small groups of reference objects.
dStart        start with this value of D.
multiple      if TRUE, stops at the rank that yields at least one match; if FALSE, continues to perform classification until exactly one match is identified.
maxDepth      Maximum number of iterations that will be attempted to perform classification.
minGroupSize  The minimal number of members comprising at least one group required to attempt classification.
objNames      Optional character identifiers for objects corresponding to margin of dmat.
keep.data     Populates thresh$distances (see findThreshold) if TRUE.
verbose       Terminal output is produced if TRUE.
index         an integer specifying an element in dmat
...            see Details
depth         specifies iteration number (not meant to be user-defined)
Details
classify performs iterative classification. See the vignette vignette for package clst for a description of the classification algorithm.
classifier performs non-iterative classification, and is typically not called directly by the user.
The functions pull and pullTab are used to remove a single element of dmat for the purpose of performing classification against the remaining elements. The value of these two functions (a list) can be passed directly to classify or classifyIter directly (see examples).

Value
classify and classifyIter return x, a list of lists, one for each iteration of the classifier. Each sub-list contains the following named elements:
depth An integer indicating the number of the iteration (where x[[i]]$depth == i)
tally a data.frame with one row for each group or reference objects. Columns below and above contain counts of reference objects with distance values greater than or less than $D$, respectively; score, containing match score $S$; match is 1 if $S \geq minScore$, 0 otherwise; and the minimum, median, and maximum values of distances to all members of the indicated group.
details a list of two matrices, named "below" and "above", itemizing each object with index $i$ in the reference set with distances below or above the distance threshold $D$, respectively. Columns include index, the index $i$; dist, the distance between the object and the query; and group, indicating the classification of the object.
matches Character vector naming groups to which query object belongs.
thresh object returned by findThreshold
params a list of input arguments and their values
input list containing copies of dvect and groups

Examples

## illustrate classification using the Iris data set
data(iris)
dmat <- as.matrix(dist(iris[,1:4], method="euclidean"))
groups <- iris$Species

## remove one element from the data set and perform classification using ## the remaining elements as the reference set
ind <- 1
cat(paste("class of "unknown" sample is Iris",groups[ind]),fill=TRUE)
cc <- classify(dmat[-ind,-ind], groups[-ind], dvect=dmat[ind, -ind])
printClst(cc)

## this operation can be performed conveinetly using the `pull` function
findThreshold

ind <- 51
cat(paste('class of "unknown" sample is Iris', groups[ind]), fill = TRUE)
cc <- do.call(classify, pull(dmat, groups, ind))
printClst(cc)
str(cc)

findThreshold

Description

Identify a distance threshold predicting whether a pairwise distance represents a comparison between objects in the same class (within-group comparison) or different classes (between-group comparison) given a matrix providing distances between objects and the group membership of each object.

Usage

findThreshold(dmat, groups, distances, method = "mutinfo", prob = 0.5, na.rm = FALSE, keep.dists = TRUE, roundCuts = 2, minCuts = 20, maxCuts = 300, targetCuts = 100, verbose = FALSE, depth = 1, ...)

partition(dmat, groups, include, verbose = FALSE)

Arguments

dmat | Square matrix of pairwise distances.
groups | Object coercible to a factor identifying group membership of objects corresponding to either edge of dmat.
include | vector (numeric or boolean) indicating which elements to retain in the output; comparisons including an excluded element will have a value of NA
distances | Optional output of partition provided in the place of dmat and groups
method | The method for calculating the threshold; only 'mutinfo' is currently implemented.
prob | Sets the upper and lower bounds of D as some quantile of the within class distances and between-class differences, respectively.
na.rm | If TRUE, excludes NA elements in groups and corresponding rows and columns in dmat. Ignored if distances is provided.
keep.dists | If TRUE, the output will contain the distances element (output of partition).
roundCuts | Number of digits to round cutoff values (see Details)
minCuts | Minimal length of vector of cutoffs (see Details).
maxCuts | Maximal length of vector of cutoffs (see Details)
targetCuts | Length of vector of cutoffs if conditions met by minCuts and maxCuts are not met (see Details).
verbose | Terminal output is produced if TRUE.
depth | Private argument used to track level of recursion.
... | Extra arguments are ignored.
findThreshold

Details

findThreshold is used internally in classify, but may also be used to calculate a starting value of SD$^2$.

partition is used to transform a square (or lower triangular) distance matrix into a data.frame containing a column of distances ($vals$) along with a factor ($comparison$) defining each distance as a within- or between-group comparison. Columns $row$ and $col$ provide indices of corresponding rows and columns of dmat.

Value

In the case of findThreshold, output is a list with elements described below. In the case of partition, output is the data.frame returned as the element named $distances$ in the output of findThreshold.

- **D** The distance threshold (distance cutoff corresponding to the PMMI).
- **pmmi** Value of the point of maximal mutual information (PMMI)
- **interval** A vector of length 2 indicating the upper and lower bounds over which values for the threshold are evaluated.
- **breaks** A data.frame with columns x and y providing candidate breakpoints and corresponding mutual information values, respectively.
- **distances** If keep.distances is TRUE, a data.frame containing pairwise distances identified as within- or between classes.
- **method** Character corresponding to input argument method.
- **params** Additional input parameters.

plotDistances, plotMutinfo

Examples

data(iris)
dmat <- as.matrix(dist(iris[,1:4], method="euclidean"))
groups <- iris$Species
thresh <- findThreshold(dmat, groups, type="mutinfo")
str(thresh)
**plotDistances**

Visualize results of `link{findThreshold}`

**Description**

The functions `plotDistances` and `plotMutinfo` are used to visualize the distance threshold calculated by `findThreshold` in the context of pairwise distances among objects in the reference set.

**Usage**

```r
plotDistances(distances, D = NA, interval = NA,
               ylab = "distances", ...)  
plotMutinfo(breaks, D = NA, interval = NA,
            xlab = "distance", ylab = "mutual information", ...)
```

**Arguments**

- `distances`: The `$distances` element of the output value of `findThreshold`
- `breaks`: The `$breaks` element of the output value of `findThreshold`
- `D`: The distance threshold
- `interval`: The range of values over which candidate values of PMMI are evaluated.
- `xlab`: Label the x axis of the plot.
- `ylab`: Label the y axis of the plot.
- `...`: Additional arguments are passed to `bwplot` (plotDistances) or `xyplot` (plotMutinfo)

**Details**

`plotDistances` produces a box-and-whisker plot contrasting within- and between-group distances.

`plotMutinfo` produces a plot of cutpoints vs mutual information scores.

**Value**

Returns a lattice grid object.

`findThreshold`

**Examples**

```r
data(iris)  
dmat <- as.matrix(dist(iris[,1:4], method="euclidean"))  
groups <- iris$Species  
thresh <- findThreshold(dmat, groups)  
do.call(plotDistances, thresh)  
do.call(plotMutinfo, thresh)
```
printClst  \hspace{1cm} \textit{Print a summary of the classifier output.}

\textbf{Description}

Prints a description of the output of \texttt{classify}.

\textbf{Usage}

\begin{verbatim}
printClst(cc, rows = 8, nameWidth = 30, groupNames)
\end{verbatim}

\textbf{Arguments}

\begin{description}
\item \texttt{cc}  \hspace{1cm} \texttt{Output of classify}
\item \texttt{rows}  \hspace{1cm} \texttt{Number of rows corresponding to groups of reference objects to show.}
\item \texttt{nameWidth}  \hspace{1cm} \texttt{Character width of group names.}
\item \texttt{groupNames}  \hspace{1cm} \texttt{a named vector containing replacement names for groups keyed by categories in groups (classify) or groupTab (classifyIter).}
\end{description}

\textbf{Value}

Output value is \texttt{NULL}; output is to stdout.

\textbf{Author(s)}

Noah Hoffman

\textbf{See Also}

\texttt{classify, classifyIter}

\textbf{Examples}

\begin{verbatim}
data(iris)
dmat <- as.matrix(dist(iris[,1:4], method="euclidean"))
groups <- iris$Species
\end{verbatim}

\textbf{scaleDistPlot}  \hspace{1cm} \textit{Annotated multidimensional scaling plots.}

\textbf{Description}

Produces annotated representations of two-dimensional multidimensional scaling plots using \texttt{cmdscale}.
scaleDistPlot

Usage

scaleDistPlot(dmat, groups, fill, X, O, indices = "no", include, display, labels, shuffleGlyphs = NA, key = "top", keyCols = 4, glyphs, xflip = FALSE, yflip = FALSE, ...)

Arguments

dmat          Square matrix of pairwise distances.
groups        Object coercible to a factor identifying group membership of objects corresponding to either edge of dmat.
fill           vector (logical or indices) of points to fill
X              vector of points to mark with an X
O              vector of points to mark with a circle
indices       label points with indices (all points if 'yes', or a subset indicated by a vector)
include       boolean or numeric vector of elements to include in call to cmdscale
display       boolean or numeric vector of elements to include in call to display
labels        list or data frame with parameters $i indicating indices and $text containing labels.
shuffleGlyphs modify permutation of shapes and colors given an integer to serve as a random seed.
key            'right' (single column), 'top' (variable number of columns), or NULL for no key
keyCols        number of columns in key
glyphs        a data.frame with columns named col and pch corresponding to elements of unique(groups)
xflip          if TRUE, flip orientation of x-axis
yflip          if TRUE, flip orientation of y-axis
...            additional arguments are passed to xyplot

Value

Returns a lattice grid object.
