Package ‘genoset’

December 21, 2016

Type Package

Title A RangedSummarizedExperiment with methods for copy number analysis

Version 1.30.0

Date 2016-07-15

Author Peter M. Haverty

Maintainer Peter M. Haverty <phaverty@gene.com>

Description GenoSet provides an extension of the RangedSummarizedExperiment class with additional API features. This class provides convenient and fast methods for working with segmented genomic data. Additionally, GenoSet provides the class RleDataFrame which stores runs of data along the genome for multiple samples and provides very fast summaries of arbitrary row sets (regions of the genome).

License Artistic-2.0

LazyLoad yes

Depends R (>= 2.10), BiocGenerics (>= 0.11.3), GenomicRanges (>= 1.17.19), SummarizedExperiment (>= 1.1.6)

Imports S4Vectors (>= 0.9.25), GenomeInfoDb (>= 1.1.3), IRanges (>= 2.5.12), methods, graphics

Suggests RUnit, knitr, BiocStyle, rmarkdown, DNAcopy, stats, BSgenome, Biostrings

Enhances parallel

ByteCompile TRUE

biocViews Infrastructure, DataRepresentation, Microarray, SNP, CopyNumberVariation

Genoset-package

Description

Load, manipulate, and plot copynumber and BAF data.

See Also

genoset-datasets

baf2mbaf

Calculate mBAF from BAF

Description

Calculate Mirrored B-Allele Frequency (mBAF) from B-Allele Frequency (BAF) as in Staaf et al., Genome Biology, 2008. BAF is converted to mBAF by folding around 0.5 so that is then between 0.5 and 1. HOM value are then made NA to leave only HET values that can be easily segmented. Values > hom.cutoff are made NA. Then, if genotypes (usually from a matched normal) are provided as the matrix 'calls' additional HOMs can be set to NA. The argument 'call.pairs' is used to match columns in 'calls' to columns in 'baf'.

Usage

baf2mbaf(baf, hom.cutoff = 0.95, calls = NULL, call.pairs = NULL)

Arguments

baf numeric matrix of BAF values
hom.cutoff numeric, values above this cutoff to be made NA (considered HOM)
calls matrix of NA, CT, AG, etc. genotypes to select HETs (in normals). Dimnames must match baf matrix.
call.pairs list, names represent target samples for HOMs to set to NA. Values represent columns in "calls" matrix.

Value

numeric matrix of mBAF values

Examples

data(genoset, package="genoset")
mabf = baf2mbaf( genoset.ds[, , "baf"], hom.cutoff=0.9 )
calls = matrix(sample(c("AT","AA","CG","GC","AT","GG"),(nrow(genoset.ds) * 2),replace=TRUE),ncol=2,dimnames=rownames(genoset.ds))
mabf = baf2mbaf( genoset.ds[, , "baf"], hom.cutoff=0.9, calls = calls, call.pairs = list(K="L",L="L")) # Sample L is matched normal for tumor sample K, M only uses hom.cutoff
mabf = baf2mbaf( genoset.ds[, , "baf"], hom.cutoff=0.9 ) # Put mbaf back into the BAFSet object
boundingIndices

Find indices of features bounding a set of chromosome ranges/genes

Description

This function is similar to findOverlaps but it guarantees at least two features will be covered. This is useful in the case of finding features corresponding to a set of genes. Some genes will fall entirely between two features and thus would not return any ranges with findOverlaps. Specifically, this function will find the indices of the features (first and last) bounding the ends of a range/gene (start and stop) such that first <= start < stop <= last. Equality is necessary so that multiple conversions between indices and genomic positions will not expand with each conversion. Ranges/genes that are outside the range of feature positions will be given the indices of the corresponding first or last index rather than 0 or n + 1 so that genes can always be connected to some data.

Usage

boundingIndices(starts, stops, positions, all.indices = FALSE)

Arguments

starts integer vector of first base position of each query range
stops integer vector of last base position of each query range
positions Base positions in which to search
all.indices logical, return a list containing full sequence of indices for each query

Details

This function uses some tricks from findIntervals, where is for k queries and n features it is O(k * log(n)) generally and ~O(k) for sorted queries. Therefore will be dramatically faster for sets of query genes that are sorted by start position within each chromosome. The index of the stop position for each gene is found using the left bound from the start of the gene reducing the search space for the stop position somewhat. boundingIndices does not check for NAs or unsorted data in the subject positions. These assumptions are safe for position info coming from a GenoSet or GRanges.

Value

integer matrix of 2 columns for start and stop index of range in data or a list of full sequences of indices for each query (see all.indices argument)

See Also

Other "range summaries": boundingIndicesByChr, rangeSampleMeans

Examples

starts = seq(10,100,10)
boundingIndices( starts=starts, stops=starts+5, positions = 1:100 )
boundingIndicesByChr

Find indices of features bounding a set of chromosome ranges/genes, across chromosomes

Description

Finds subject ranges corresponding to a set of genes (query ranges), taking chromosome into account. Specifically, this function will find the indices of the features (first and last) bounding the ends of a range/gene (start and stop) such that first <= start < stop <= last. Equality is necessary so that multiple conversions between indices and genomic positions will not expand with each conversion. Ranges/genes that are outside the range of feature positions will be given the indices of the corresponding first or last index on that chromosome, rather than 0 or n + 1 so that genes can always be connected to some data. Checking the left and right bound for equality will tell you when a query is off the end of a chromosome.

Usage

boundingIndicesByChr(query, subject)

Arguments

query

GRanges or something coercible to GRanges

subject

GenomicRanges

Details

This function uses some tricks from findIntervals, where is for k queries and n features it is O(k * log(n)) generally and ~O(k) for sorted queries. Therefore will be dramatically faster for sets of query genes that are sorted by start position within each chromosome. The index of the stop position for each gene is found using the left bound from the start of the gene reducing the search space for the stop position somewhat.

This function differs from boundingIndices in that 1. it uses both start and end positions for the subject, and 2. query and subject start and end positions are processed in blocks corresponding to chromosomes.

Both query and subject must be in at least weak genome order (sorted by start within chromosome blocks).

Value

integer matrix with two columns corresponding to indices on left and right bound of queries in subject

See Also

Other "range summaries": boundingIndices, rangeSampleMeans
bounds2Rle  

Convert bounding indices into a Rle

Description

Given a matrix of first/last indices, like from boundingIndicesByChr, and values for each range, convert to a Rle. This function takes the expected length of the Rle, n, so that any portion of the full length not covered by a first/last range will be a run with the value NA. This is typical in the case where data is segmented with CBS and some of the data to be segmented is NA.

Usage

bounds2Rle(bounds, values, n)

Arguments

bounds  

matrix, two columns, with first and last index, like from boundingIndicesByChr

values  

ANY, some value to be associated with each range, like segmented copy number.

n  

integer, the expected length of the Rle, i.e. the number of features in the genome/target ranges processed by boundingIndicesByChr.

Value

Rle

See Also

Other "segmented data": rangeSegMeanLength, runCBS, segPairTable, segTable, segs2Granges, segs2RleDataFrame, segs2Rle

calcGC  

Calculate GC Percentage in windows

Description

Local GC content can be used to remove GC artifacts from copynumber data (see Diskin et al, Nucleic Acids Research, 2008, PMID: 18784189). This function will calculate GC content fraction in expanded windows around a set of ranges following example in http://www.bioconductor.org/help/course-materials/2012/useR2012/Bioconductor-tutorial.pdf. Currently all ranges are tabulated, later I may do letterFrequencyInSlidingWindow for big windows and then match to the nearest.

Usage

calcGC(object, bsgenome, expand = 1e+06, bases = c("G", "C"))

Arguments

object  

GenomicRanges or GenoSet

bsgenome  

BSgenome, like Hsapiens from BSgenome.Hsapiens.UCSC.hg19 or DNAStringSet.

expand  

scalar integer, amount to expand each range before calculating gc

bases  

character, alphabet to count, usually c("G", "C"), but "N" is useful too
calcGC2

Value
numeric vector, fraction of nucleotides that are G or C in expanded ranges of object

Examples

## Not run: library(BSgenome.Hsapiens.UCSC.hg19)
## Not run: gc = calcGC(genoset.ds, Hsapiens)

calcGC2 Calculate GC Percentage in sliding window

Description
Local GC content can be used to remove GC artifacts from copynumber data (see Diskin et al, Nucleic Acids Research, 2008, PMID: 18784189). This function will calculate GC content fraction in expanded windows around a set of ranges following example in http://www.bioconductor.org/help/course-materials/2012/useR2012/Bioconductor-tutorial.pdf. Values are as.integer( 1e4 * fraction ) for space reasons.

Usage
calcGC2(dna)

Arguments
dna BSgenome or DNAStringSet

Value
SimpleRleList, integer 1e4 * GC fraction, chromosomes 1:22, X and Y

Examples

## Not run: library(BSgenome.Hsapiens.UCSC.hg19)
## Not run: gc = calcGC2(Hsapiens)

chr Chromosome name for each feature

Description
Get chromosome name for each feature. Returns character.

Usage
chr(object)

## S4 method for signature 'GenoSet'
chr(object)

## S4 method for signature 'GenomicRanges'
chr(object)
chrIndices

Arguments

object GRanges GenoSet

Value

character vector of chromosome positions for each feature

Examples

data(genoset, package="genoset")
chr(genoset.ds) # c("chr1", "chr1", "chr1", "chr3", "chr3", "chrX", "chrX", "chrX")
chr(rowRanges(genoset.ds)) # The same

chrIndices

Get a matrix of first and last index of features in each chromosome

Description

Sometimes it is handy to know the first and last index for each chr. This is like chrInfo but for feature indices rather than chromosome locations. If chr is specified, the function will return a sequence of integers representing the row indices of features on that chromosome.

Usage

chrIndices(object, chr = NULL)

## S4 method for signature 'GenoSetOrGenomicRanges'
chrIndices(object, chr = NULL)

Arguments

object GenoSet or GRanges

chr character, specific chromosome name

Value

data.frame with "first" and "last" columns

Examples

data(genoset, package="genoset")
chrIndices(genoset.ds)
chrIndices(rowRanges(genoset.ds)) # The same
**chrInfo**

Get chromosome start and stop positions

**Description**

Provides a matrix of start, stop and offset, in base numbers for each chromosome.

**Usage**

\[
\text{chrInfo(object)}
\]

**Arguments**

- **object** A GenoSet object or similar

**Value**

list with start and stop position, by ordered chr

**Examples**

```r
data(genoset, package="genoset")
chrInfo(genoset.ds)
chrInfo(rowRanges(genoset.ds))  # The same
```

---

**chrNames**

Get list of unique chromosome names

**Description**

Get list of unique chromosome names

**Usage**

\[
\text{chrNames(object)}
\]

**Examples**

```r
chrNames(object)
```

```r
<< S4 method for signature 'GenoSet'
chrNames(object)
```

```r
<< S4 method for signature 'GenomicRanges'
chrNames(object)
```

```r
chrNames(object) <- value
```

```r
<< S4 replacement method for signature 'GenoSet'
chrNames(object) <- value
```

```r
<< S4 replacement method for signature 'GenomicRanges'
chrNames(object) <- value
```
**Arguments**

- **object** GenomicRanges or GenoSet
- **value** return value of chrNames

**Value**

character vector with names of chromosomes

**Examples**

```r
data(genoset,package="genoset")
chrNames(genoset.ds)  # c("chr1","chr3","chrX")
chrNames(rowRanges(genoset.ds))  # The same
chrNames(genoset.ds) = sub("^chr","",chrNames(genoset.ds))
```

**chrOrder**

Order chromosome names in proper genome order

**Description**

Chromosomes make the most sense ordered by number, then by letter.

**Usage**

`chrOrder(chr.names)`

**Arguments**

- **chr.names** character, vector of unique chromosome names

**Value**

character vector of chromosome names in proper order

**See Also**

Other "genome ordering": `isGenomeOrder`, `toGenomeOrder`

**Examples**

```r
chrOrder(c("chr5","chrX","chr3","chr7","chrY"))  # c("chr3","chr5","chr7","chrX","chrY")
```
**Description**

Get indices of first and last element in each chromosome.

**Usage**

`chrPartitioning(object)`

**Arguments**

- `object`: GenoSet or GenomicRanges

**Value**

PartitioningByEnd

---

**Description**

Utility function for converting copynumber units (2 is normal) to log2ratio units (two is normal). If ploidy is provided lr is log2(cn/ploidy), otherwise log2(cn/2).

**Usage**

`cn2lr(x, ploidy)`

**Arguments**

- `x`: numeric vector or matrix, or DataFrame with numeric-like columns (Rle typically). Assumed to be in copynumber units.
- `ploidy`: numeric, of length ncol(x). Ploidy of each sample.

**Value**

data of same type as "x" transformed into log2ratio units
See Also

lr2cn

fixSegNAs  Fix NA runs in a Rle

Description

Fix NA runs in a Rle when the adjacent runs have equal values

Usage

fixSegNAs(x, max.na.run = 3)

Arguments

  x  Rle to be fixed
  max.na.run  integer, longest run of NAs that will be fixed

Value

Rle

gcCorrect  Correct copy number for GC content

Description

Copy number estimates from various platforms show "Genomic Waves" (Diskin et al., Nucleic Acids Research, 2008, PMID: 18784189) where copy number trends with local GC content. This function regresses copy number on GC percentage and removes the effect (returns residuals). GC content should be smoothed along the genome in wide windows >= 100kb.

Usage

gcCorrect(ds, gc, retain.mean = TRUE)

Arguments

  ds  numeric matrix of copynumber or log2ratio values, samples in columns
  gc  numeric vector, GC percentage for each row of ds, must not have NAs
  retain.mean  logical, center on zero or keep same mean?

Value

numeric matrix, residuals of ds regressed on gc

Examples

gc = runif(n=100, min=1, max=100)
ds = rnorm(100) + (0.1 * gc)
gcCorrect(ds, gc)
genome

Get and set the genome universe annotation.

Description
Genome version

Arguments
x GenoSet

Details
The genome positions of the features in locData. The UCSC notation (e.g. hg18, hg19, etc.) should be used.

Value
character, e.g. hg19

Examples
data(genoset)
genoSet
genome(genoset.ds) = "hg19"

genomeAxis

Label axis with base pair units

Description
Label an axis with base positions

Usage
genoSet

Arguments
locs GenomicRanges to be used to draw chromosome boundaries, if necessary. Usually rowRanges slot from a GenoSet.
side integer side of plot to put axis
log logical Is axis logged?
do.other.side logical, label non-genome side with data values at tick marks?

Details
Label a plot with Mb, kb, bp as appropriate, using tick locations from aXTicks
Value
nothing

See Also
Other "genome plots": genoPlot

Examples

data(genoset, package="genoset")
genoPlot(genoPos(genoset.ds), genoset.ds[,1, "baf"])
genomeAxis( locs=rowRanges(genoset.ds) ) # Add chromosome names and boundaries to a plot assuming genome all
genomeAxis( locs=rowRanges(genoset.ds), do.other.side=FALSE ) # As above, but do not label y-axis with data
genomeAxis() # Add nucleotide position in sensible units assuming genome along x-axis

Description
Plot location data and chromosome boundaries from a GenoSet or GRanges object against data
from a numeric or Rle. Specifying a chromosome name and optionally a 'xlim' will zoom into one
chromosome region. If more than one chromosome is present, the chromosome boundaries will be
marked. Alternatively, for a numeric x and a numeric or Rle y, data in y can be plotted at genome
positions x. In this case, chromosome boundaries can be taken from the argument locs. If data for
y-axis comes from a Rle lines are plotted representing segments. X-axis tickmarks will be labeled
with genome positions in the most appropriate units.

Usage
genoPlot(x, y, ...)

Arguments
x GenoSet (or descendant) or GRanges
y numeric or Rle
... Additional plotting args
add Add plot to existing plot
**genoPos**

<table>
<thead>
<tr>

**Value**

TRUE

**Methods**

signature(x = "GenoSetOrGenomicRanges", y = "ANY") Plot feature locations and data from one sample.

signature(x = "numeric", y = "numeric") Plot numeric location and a vector of numeric data.

signature(x = "numeric", y = "Rle") Plot numeric location and a vector of Rle data. Uses lines for Rle runs.

**See Also**

Other "genome plots": genoAxis

**Examples**

data(genoset, package="genoset")

```r
  genoPlot( x=genoset.ds, y=genoset.ds[,1,"lrr"] )
  genoPlot( genoPos(genoset.ds), genoset.ds[,1,"lrr"], locs=rowRanges(genoset.ds) )  # The same
  genoPlot( 1:10, Rle(c(rep(0,5),rep(3,4),rep(1,1))) )
```

---

**Description**

Get base positions of features in genome-scale units.

**Usage**

`genoPos(object)`

```r
## S4 method for signature 'GenoSetOrGenomicRanges'
  genoPos(object)
```

Get base positions of array features in bases counting from the start of the genome. Chromosomes are ordered numerically, when possible, then lexically.
GenoSet

Arguments

object A GenoSet object or a GenomicRanges object

Value

numeric position of each feature in whole genome units, in original order

Examples

data(genoset, package="genoset")
head(genoPos(genoset.ds))
head(genoPos(rowRanges(genoset.ds))) # The same

Description

This function is the preferred method for creating a new GenoSet object. Currently, a GenoSet is simply a RangedSummarizedExperiment with some API changes and extra methods. Therefore, a GenoSet must always have a rowRanges.

Usage

GenoSet(rowRanges, assays, colData, metadata = list())

## S4 method for signature 'GenoSet'
lengths(x)
locData(object, ...) <- value
locData(object)

Arguments

rowRanges GenomicRanges, not a GenomicRangesList
assays list, SimpleList or matrix-like object
colData a data.frame or DataFrame of sample metadata with rownames matching the colnames of the matrices in assays
metadata a list of any other data you want to attach to the GenoSet object
x A GenoSet

Details

locations. Rownames are required to match featureNames.

Value

A GenoSet object
GenoSet-class

Examples

```r
test.sample.names = LETTERS[11:13]
probe.names = letters[1:10]
assays=list(matrix(31:60,nrow=10,ncol=3,dimnames=list(probe.names,test.sample.names)))
rowRanges=GRanges(ranges=IRanges(start=1:10,width=1,names=probe.names),seqnames=c(rep("chr1",4),rep("chr3",2),rep("chrX",4)),
colData=data.frame(matrix(LETTERS[1:15],nrow=3,ncol=5,dimnames=list(test.sample.names,letters[1:5])))
gse=SummarizedExperiment(rowRanges=rowRanges,assays=assays,colData=colData,metadata=metadata)

gs = GenoSet(rowRanges, assays, colData)
```

Description

GenoSet extends RangedSummarizedExperiment by adding some additional methods to the API. Examples include subsetting rows with a GenomicRanges and combining this with access to assays like genoset[i,j,assay].

Extends

Class RangedSummarizedExperiment, directly.

Methods

```r
[  signature(x = "GenoSet", i = "ANY", j = "ANY", drop = "ANY"): ... 
[  signature(x = "GenoSet", i = "character", j = "ANY", drop = "ANY"): ... 
[<- signature(x = "GenoSet", i = "ANY", j = "ANY", value = "ANY"): ...
chr signature(object = "GenoSet"): ...
chrNames signature(object = "GenoSet"): ...
dim signature(object = "GenoSet"): ...
genoPlot signature(x = "GenoSet", y = "ANY"): ...
rowRanges signature(object = "GenoSet"): ...
names signature(x = "GenoSet"): ...
ranges signature(x = "GenoSet"): ...
chrInfo signature(x = "GenoSet"): ...
chrIndices signature(x = "GenoSet"): ...
show signature(object = "GenoSet"): ...
toGenomeOrder signature(ds = "GenoSet"): ...
isGenomeOrder signature(ds = "GenoSet"): ...
assays signature(x = "GenoSet"): ...
assay signature(x = "GenoSet", i="ANY"): ...
assay<- signature(x = "GenoSet", i="ANY",value="ANY"): ...
assayNames signature(x = "GenoSet"): ...
colData signature(x = "GenoSet"): ...
locData signature(x = "GenoSet"): ...
locData<- signature(x = "GenoSet",value="GenomicRanges"): ...
```
See Also

GenoSet

Examples

```r
class("GenoSet")
test.sample.names = LETTERS[11:13]
probe.names = letters[1:10]
assays = list(matrix(31:60, nrow=10, ncol=3, dimnames=list(probe.names, test.sample.names)))
rowRanges = GRanges(ranges = IRanges(start=1:10, width=1, names=probe.names), seqnames = c(rep("chr1", 4), rep("chr3", 2), rep("chrX", 4)))
colData = data.frame(matrix(LETTERS[1:15], nrow=3, ncol=5, dimnames=list(test.sample.names, letters[1:5])))
rse = SummarizedExperiment(rowRanges=rowRanges, assays=assays, colData=colData)
s = GenoSet(rowRanges, assays, colData)
```

Description

A GenoSet object the 'baf' (B-Allele Frequency) and 'lrr' (Log-R Ratio) assay matrices. The 'lrr' assay matrix contains DNA copy number on the scale of tumor/ploidy and the 'baf' assay matrix contains data in the range 0 to 1 where 0 indicates the AA genotype, 0.5 indicates the AB genotype and 1 indicates the BB genotype.

Source

Simulated data

isGenomeOrder

Description

Checks that rows in each chr are ordered by start. If strict=TRUE, then chromosomes must be in order specified by chrOrder. isGenomeOrder for GRanges differs from order in that it orders by chromosome and start position only, rather than chromosome, strand, start, and width.

Usage

```r
isGenomeOrder(ds, strict = TRUE)
```

Arguments

- `ds`: GenoSet or GRanges
- `strict`: logical, should space/chromosome order be identical to that from chrOrder?
isGenomeOrder

Value

logical

See Also

Other "genome ordering": chrOrder, toGenomeOrder

Examples

data(genoset, package="genoset")
isGenomeOrder( rowRanges(genoset.ds) )

isGenomeOrder

Check if a GRanges or GenoSet is in genome order

Description

Checks that rows in each chr are ordered by start. If strict=TRUE, then chromosomes must be in order specified by chrOrder. isGenomeOrder for GRanges differs from order in that it orders by chromosome and start position only, rather than chromosome, strand, start, and width.

Usage

isGenomeOrder(ds, strict = TRUE)

Arguments

ds GenoSet or GRanges
strict logical, should space/chromosome order be identical to that from chrOrder?

Value

logical

See Also

Other "genome ordering": chrOrder, toGenomeOrder

Examples

data(genoset, package="genoset")
isGenomeOrder( rowRanges(genoset.ds) )
1r2cn

Take vector or matrix of log2 ratios, convert to copynumber

Description
Utility function for converting log2ratio units (zero is normal) to copynumber units (two is normal)

Usage
1r2cn(x)

Arguments
x numeric data in log2ratio values

Value
data of same type as "x" transformed into copynumber units

See Also
cn2lr

modeCenter
Center continuous data on mode

Description
Copynumber data distributions are generally multi-modal. It is often assumed that the tallest peak represents "normal" and should therefore be centered on a log2ratio of zero. This function uses the density function to find the mode of the dominant peak and subtracts that value from the input data.

Usage
modeCenter(ds)

Arguments
ds numeric matrix

Value
numeric matrix

Examples
modeCenter( matrix( rnorm(150, mean=0), ncol=3 ))
### nrow,GenomicRanges-method

#### GenomicRanges API Additions

**Description**

I have extended the API for GenomicRanges a bit so that genoset and GenomicRanges can have the same API, at least as far as genome location based features go.

**Usage**

```r
## S4 method for signature 'GenomicRanges'
nrow(x)
```

**Arguments**

- `x` A GenomicRanges

---

**numCallable**

*Count Rle positions >= min*

**Description**

For Rle coverage vector, count number of positions where value >= min, think callable bases.

**Usage**

```r
numCallable(rle, bounds, min)
```

**Arguments**

- `rle` integer Rle, no NAs
- `bounds` IRanges or matrix, positions in Rle to consider. If bounds is a matrix, the first two columns are used as start and end.
- `min` scalar integer, count Rle positions >= this value.

**Value**

integer vector of length nrow(bounds)
pos,GenoSetOrGenomicRanges-method

*Chromosome position of features*

**Description**
Get chromosome position of features/ranges. Defined as floor of mean of start and end.

**Usage**
```r
## S4 method for signature 'GenoSetOrGenomicRanges'
pos(x)
```

**Arguments**
- `x` : GRanges GenoSet

**Value**
numeric vector of feature positions within a chromosome

**Examples**
```r
data(genoset,package="genoset")
pos(genoset.ds) # 1:10
pos(rowRanges(genoset.ds)) # The same
```

---

rangeSampleMeans

*Average features in ranges per sample*

**Description**
This function takes per-feature genomic data and returns averages for each of a set of genomic ranges. The most obvious application is determining the copy number of a set of genes. The features corresponding to each gene are determined with boundingIndices such that all features with the bounds of a gene (overlaps). The features on either side of the gene unless those positions exactly match the first or last base covered by the gene. Therefore, genes falling between two features will at least cover two features. Range bounding is performed by the boundingIndices function.

**Usage**
```r
rangeSampleMeans(query, subject, assay.element, na.rm = FALSE)
```

**Arguments**
- `query` : GRanges object representing genomic regions (genes) to be averaged.
- `subject` : A GenoSet object or derivative
- `assay.element` : character, name of element in assayData to use to extract data
- `na.rm` : scalar logical, ignore NAs?
rangeSegMeanLength

Value
numeric matrix of features in each range averaged by sample

See Also
Other "range summaries": boundingIndicesByChr, boundingIndices

Examples

data(genoset)
my.genes = GRanges( ranges=IRanges(start=c(35e6,128e6),end=c(37e6,129e6),names=c("HER2","MYC")), seqnames=c("chr17","chr8") )
rangeSampleMeans( my.genes, genoset.ds, "lrr" )

rangeSegMeanLength Get segment widths

Description
The width of a genomic segment helps inform us about the importance of a copy number value. Focal amplifications are more interesting than broad gains, for example. Given a range of interesting regions (i.e. genes) this function determines all genomics segments covered by each gene and returns the average length of the segments covered by each gene in each sample. Often only a single segment covers a given gene in a given sample.

Usage

rangeSegMeanLength(range.gr, segs)

## S4 method for signature 'GRanges,list'
rangeSegMeanLength(range.gr, segs)

## S4 method for signature 'GRanges,data.frame'
rangeSegMeanLength(range.gr, segs)

Arguments

range.gr GRanges, genome regions of interest, usually genes
segs data.frame of segments, like from segTable, or a list of these

Value
named vector of lengths, one per item in range.gr, or a range x length(segs) of these if segs is also list-like.

See Also
Other "segmented data": bounds2Rle, runCBS, segPairTable, segTable, segs2Granges, segs2RleDataFrame, segs2Rle
rbindDataframe  

*A fast method for concatenating data.frames*

**Description**

Performs the same action as `do.call(rbind, list_of_dataframes)`, but dramatically faster. Part of the speed comes from assuming that all of the data.frames have the same column names and types. If desired, an additional factor column can be added that specifies the original list element associated with each row. The argument ‘element.colname’ is used to name this column.

**Usage**

```r
rbindDataframe(dflist, element.colname)
```

**Arguments**

- `dflist` list of data.frames
- `element.colname` scalar character, name for additional factor column giving the name of the element of ‘dflist’ corresponding to each row. ‘dflist’ must be named to use this feature.

**Details**

For a list of 1000 data.frames with 884 rows and 12 columns ‘rbindDataframe’ takes 0.553s and ‘do.call(rbind,x)’ takes 327.304s, a 600X speedup. This pure-R solution is made possible by the lovely shallow copy features Michael Lawrence has added to base R.

**Value**

data.frame

---

readGenoSet  

*Load a GenoSet from a RData file*

**Description**

Given a rds file or a rda file with one GenoSet, load it, and return. Objects that pre-date the switch to a RangedSummarizedExperiment internal representation (V 1.29.0) are automatically switched to the new format.

**Usage**

```r
readGenoSet(path)
```

**Arguments**

- `path` character, path to rds or rda file
Value

GenoSet or related object (only object in RData file)

Examples

```r
## Not run: ds = readGenoSet("/path/to/genoset.RData")
## Not run: ds = readGenoSet("/path/to/genoset.rda")
## Not run: ds = readGenoSet("/path/to/genoset.rds")
```

Description

The RleDataFrame class serves to hold a collection of Run Length Encoded vectors (Rle objects) of the same length. For example, it could be used to hold information along the genome for a number of samples, such as sequencing coverage, DNA copy number, or GC content. This class inherits from both DataFrame and SimpleRleList (one of the AtomicVector types). This means that all of the usual subsetting and applying functions will work. Also, the AtomicList functions, like mean and sum, that automatically apply over the list elements will work. The scalar mathematical AtomicList methods can make this class behave much like a matrix (see Examples).

New objects can be created with the RleDataFrame constructor: `RleDataFrame(..., row.names=NULL)`, where ... can be a list of Rle objects, or one or more individual Rle objects.

Use in Biobase eSet objects

The genoset class defines an `annotatedDataFrameFrom` method for DataFrame, which makes it possible to include DataFrames as assayData elements. The column names for DataFrame cannot be NULL, which makes it impossible to use them as assays in SummarizedExperiment at this time.

Row and Column Summaries

These objects will sometimes be in place of a matrix, as in the eSet example above. It is convenient to have some of the summarization methods for matrices. Each of these methods takes an RleDataFrame and returns a single Rle. The time required is similar to that required for a matrix. For an RleDataFrame x,

- `rowSums`: Sum across 'rows'.
- `rowMeans`: Means across 'rows'.
- `colSums`: Sum each Rle. This is just the `sum` method for SimpleRleList.
- `colSums`: Mean of each Rle. This is just the `mean` method for SimpleRleList.

Slots

- `rownames`: Object of class "characterORNULL" Names to describe each row of the DataFrame. These may end up taking more space than your collection of Rle objects, so consider leaving this NULL.
- `nrows`: Object of class "integer" Number of rows.
- `elementType`: Object of class "character" Notes that elements of the internal list are Rle objects.
- `elementMetadata`: Object of class "DataTableORNULL" Metadata on the elements, see DataFrame.
- `metadata`: Object of class "list" Metadata on the whole object, see DataFrame.
- `listData`: Object of class "list" Base list containing the Rle objects.
Extends

Class "SimpleRleList", directly. Class "DataFrame", directly.

Methods

as.matrix signature(x = "RleDataFrame"): Convert to matrix.
coerce signature(x = "RleDataFrame"): Convert to other classes.
colMeans signature(x = "RleDataFrame"): Mean of each column.
colSums signature(x = "RleDataFrame"): Sum of each column.
rowMeans signature(x = "RleDataFrame"): Mean of each 'row'.
rowSums signature(x = "RleDataFrame"): Sum of each 'row'.
show signature(object = "RleDataFrame"): Short and pretty description of an object of this type.

Author(s)

Peter M. Haverty, design suggestion from Michael Lawrence.

sum(df)
df + 5
log2(df) - 1

## Row and Column Summaries
rowSums(df)
colSums(df)
rowMeans(df)
colMeans(df)

## Coercion
as(df, "matrix")
RleDataFrame-views

```
as(df, "list")
as(df, "RleList")
as(df, "DataFrame")
as(df, "data.frame")
```

---

**Description**

These methods mirror the viewMeans type functions from IRanges for SimpleRleList. They differ in that they work on an RleDataFrame and an IRanges directly and also have a simplify argument. This works out to be faster (compute-wise) and also convenient.

Still, an RleDataFrame inherits from SimpleRleList, so all of the views functions will work.

**Usage**

```
rangeSums(x, bounds, na.rm=FALSE, simplify=TRUE)
rangeMeans(x, bounds, na.rm=FALSE, simplify=TRUE, ...)
rangeMins(x, bounds, na.rm=FALSE, simplify=TRUE)
rangeMaxs(x, bounds, na.rm=FALSE, simplify=TRUE)
rangeWhichMins(x, bounds, na.rm=FALSE, simplify=TRUE)
rangeWhichMaxs(x, bounds, na.rm=FALSE, simplify=TRUE)
```

**Arguments**

- `x` RleDataFrame
- `bounds` Matrix with two columns or IRanges representing ranges of rows of `x` to process. If `bounds` is a matrix, an IRanges is constructed assuming the first two columns represent the start and end of the ranges. The names for the IRanges is taken from the rownames of the matrix. Such a matrix can constructed with boundingIndicesByChr and is the preferred input.
- `na.rm` Scalar logical. Ignore NAs in calculations?
- `simplify` Scalar logical. Simplify result? If TRUE, the return value will be a vector or matrix. For a single view, a vector will be returned. Otherwise a matrix with one row per view and one column per column of `x` will be returned. If FALSE, the return value will be a list of length `ncol(x)` of vectors of length `nrow(bounds)`.
- `...` Additional arguments for other methods.

**Details**

The "range" name prefixes here serve to differentiate these functions from the "view" functions. This may change. I will be asking the IRanges team to add "..." and "simplify" to the "view" methods so that I can just make additional methods for RleDataFrame.

**Value**

With `simplify == TRUE`, a vector for single view or a matrix otherwise. When `simplify == FALSE`, a list of vectors length `ncol(x)` where each element is of length `nrows(bounds)`.

rangeWhichMins(df,bounds)
rangeWhichMaxs(df,bounds)

# RleDataFrame isa SimpleRleList, so all the IRanges view* methods work too:
v = RleViewsList( lapply( df, Views, start=bounds ) )
viewMeans(v)

runCBS

Run CBS Segmentation

Description

Utility function to run CBS’s three functions on one or more samples

Usage

runCBS(data, locs, return.segs = FALSE, n.cores = 1, smooth.region = 2,
        outlier.SD.scale = 4, smooth.SD.scale = 2, trim = 0.025,
        alpha = 0.001)

Arguments

data numeric matrix with continuous data in one or more columns
locs GenomicRanges, like rowRanges slot of GenoSet
return.segs logical, if true list of segment data.frames return, otherwise a DataFrame of Rle vectors. One Rle per sample.
n.cores numeric, number of cores to ask mclapply to use
smooth.region number of positions to left and right of individual positions to consider when smoothing single point outliers
outlier.SD.scale number of SD single points must exceed smooth.region to be considered an outlier
segPairTable

smooth.SD.scale
floor used to reset single point outliers
trim
test fraction of sample to smooth
alpha
test pvalue cutoff for calling a breakpoint

Details
Takes care of running CBS segmentation on one or more samples. Makes appropriate input, smooths outliers, and segment

Value
data frame of segments from CBS

See Also
Other "segmented data": bounds2Rle, rangeSegMeanLength, segPairTable, segTable, segs2Granges, segs2RleDataFrame, segs2Rle

Examples
sample.names = paste("a",1:2,sep="")
probe.names = paste("p",1:30,sep="")
ds = matrix(c(c(rep(5,20),rep(3,10)),c(rep(2,10),rep(7,10),rep(9,10))),ncol=2,dimnames=list(probe.names,sample.names))
locs = GRanges(ranges=IRanges(start=c(1:20,1:10),width=1,names=probe.names),seqnames=paste("chr",c(rep(1,20),rep(2,10)),sep=""))
seg.rle.result = RleDataFrame( a1 = Rle(c(rep(5,20),rep(3,10))), a2 = Rle(c(rep(2,10),rep(7,10),rep(9,10))))
seg.list.result = list(
a1 = data.frame( ID=rep("a1",2), chrom=factor(c("chr1","chr2")), loc.start=c(1,1), loc.end=c(20,10), num.mark=c(20,10), seg.mean=c(5,3), stringsAsFactors=FALSE),
a2 = data.frame( ID=rep("a2",3), chrom=factor(c("chr1","chr2")), loc.start=c(1,11,1), loc.end=c(10,20,10), num.mark=c(10,10,10), seg.mean=c(2,7,9), stringsAsFactors=FALSE))
runCBS(ds,locs) # Should give seg.rle.result
runCBS(ds,locs,return.segs=TRUE) # Should give seg.list.result

segPairTable

Convert Rle objects to tables of segments

Description
Like segTable, but for two Rle objects. Takes a pair of Rle or DataFrames with Rle columns and makes one or more dataframes with bounds of each new segment. Rle objects are broken up so that each resulting segment has one value from each Rle. For a DataFrame, the argument stack combines all of the individual dataframes into one large dataframe and adds a "Sample" column of sample ids.

Usage
segPairTable(x, y, ...)

## S4 method for signature 'Rle,Rle'
segPairTable(x, y, locs = NULL, chr.ind = NULL,
segPairTable

start = NULL, end = NULL, factor.chr = TRUE)

## S4 method for signature 'DataFrame,DataFrame'
segPairTable(x, y, locs, stack = FALSE,
             factor.chr = TRUE)

Arguments

x Rle or list/DataFrame of Rle vectors
y Rle or list/DataFrame of Rle vectors
... in generic, extra arguments for methods
locs GenomicRanges with rows corresponding to rows of df
chr.ind matrix, like from chrIndices method
start integer, vector of feature start positions
end integer, vector of feature end positions
factor.chr scalar logical, make 'chrom' column a factor?
stack logical, rbind list of segment tables for each sample and add "Sample" column?

Details

For a Rle, the user can provide locs or chr.ind, start and stop. The latter is surprisingly much faster and this is used in the DataFrame version.

Value

one or a list of data.frames with columns chrom, loc.start, loc.end, num.mark, seg.mean

See Also

Other "segmented data": bounds2Rle, rangeSegMeanLength, runCBS, segTable, segs2Granges, segs2RleDataFrame, segs2Rle

Examples

cn = Rle(c(3,4,5,6),rep(3,4))
loh = Rle(c(2,4,6,8,10,12),rep(2,6))
start = c(9:11,4:9,15:17)
end = start
locs = GRanges(IRanges(start=start,end=end),seqnames=c(rep("chr1",3),rep("chr2",6),rep("chr3",3)))
segPairTable(cn,loh,locs)
segs2Granges

**Description**
GenoSet contains a number of functions that work on segments. Many work on a data.frame of segments, like segTable and runCBS. This function converts one of these tables in a GRanges. The three columns specifying the ranges become the GRanges and all other columns go into the ‘mcols’ portion of the GRanges object.

**Usage**
segs2Granges(segs)

**Arguments**
- **segs** data.frame with loc.start, loc.end, and chrom columns, like from segTable or runCBS

**Value**
GRanges

**See Also**
Other "segmented data": bounds2Rle, rangeSegMeanLength, runCBS, segPairTable, segTable, segs2RleDataFrame, segs2Rle

segs2Rle

**Description**
Take output of CBS, make Rle representing all features in 'locs' ranges. CBS output contains run length and run values for genomic segments, which could very directly be converted into a Rle. However, as NA values are often removed, especially for mBAF data, these run lengths do not necessarily cover all features in every sample. Using the start and top positions of each segment and the location of each feature, we can make a Rle that represents all features.

**Usage**
segs2Rle(segs, locs)

**Arguments**
- **segs** data.frame of segments, formatted as output of segment function from DNAcopy package
- **locs** GenomicRanges, like rowRanges slot of a GenoSet
segs2RleDataFrame

Value

Rle with run lengths and run values covering all features in the data set.

See Also

Other "segmented data": bounds2Rle, rangeSegMeanLength, runCBS, segPairTable, segTable, segs2Granges, segs2RleDataFrame

Examples

data(genoset,package="genoset")
segs = runCBS( genoset.ds[, , "lrr"], rowRanges(genoset.ds), return.segs=TRUE )
segs2Rle( segs[[1]], rowRanges(genoset.ds) ) # Take a data.frame of segments, say from DNAcopy's segment function

segs2RleDataFrame CBS segments to probe matrix

Description

Given segments, make an RleDataFrame of Rle objects for each sample

Usage

segs2RleDataFrame(seg.list, locs)

Arguments

seg.list list, list of data frames, one per sample, each is result from CBS
locs rowRanges from a GenoSet object

Details

Take table of segments from CBS, convert DataTable of Rle objects for each sample.

Value

RleDataFrame with nrows same as locs and one column for each sample

See Also

Other "segmented data": bounds2Rle, rangeSegMeanLength, runCBS, segPairTable, segTable, segs2Granges, segs2Rle

Examples

data(genoset,package="genoset")
seg.list = runCBS( genoset.ds[, , "lrr"], rowRanges(genoset.ds), return.segs=TRUE )
segs2RleDataFrame( seg.list, rowRanges(genoset.ds) ) # Loop segs2Rle on list of data.frames in seg.list
segTable

Convert Rle objects to tables of segments

Description

Like the inverse of segs2Rle and segs2RleDataFrame. Takes a Rle or a RleDataFrame and the rowRanges both from a GenoSet object and makes a list of data.frames each like the result of CBS’s segment. Note the loc.start and loc.stop will correspond exactly to probe locations in rowRanges and the input to segs2RleDataFrame are not necessarily so. For a DataFrame, the argument stack combines all of the individual data.frames into one large data.frame and adds a "Sample" column of sample ids.

Usage

segTable(object, ...)

## S4 method for signature 'Rle'
segTable(object, locs = NULL, chr.ind = NULL, start = NULL, end = NULL, factor.chr = TRUE)

## S4 method for signature 'DataFrame'
segTable(object, locs, factor.chr = TRUE, stack = FALSE)

Arguments

object Rle or RleDataFrame

... in generic, for extra args in methods

locs GenomicRanges with rows corresponding to rows of df

chr.ind matrix, like from chrIndices method

start integer, vector of feature start positions

def integer, vector of feature end positions

factor.chr scalar logical, make 'chrom' column a factor?

stack logical, rbind list of segment tables for each sample and add "Sample" column?

Details

For a Rle, the user can provide locs or chr.ind, start and stop. The latter is surprisingly much faster and this is used in the DataFrame version.

Value

one or a list of data.frames with columns chrom, loc.start, loc.end, num.mark, seg.mean

See Also

Other "segmented data": bounds2Rle, rangeSegMeanLength, runCBS, segPairTable, segs2Granges, segs2RleDataFrame, segs2Rle
Examples

```r
data(genoset, package="genoset")
seg.list = runCBS( genoset.ds[, , "lrr"], rowRanges(genoset.ds), return.segs=TRUE )
df = segs2RleDataFrame( seg.list, rowRanges(genoset.ds) ) # Loop segs2Rle on list of data.frames in seg.list
genoset.ds[, , "lrr.segs"] = df
segTable( df, rowRanges(genoset.ds) )
segTable( genoset.ds[, , "lrr.segs"], rowRanges(genoset.ds) )
segTable( genoset.ds[, 1, "lrr.segs"], rowRanges(genoset.ds), colnames(genoset.ds)[1] )
```

toGenomeOrder

Set a GRanges or GenoSet to genome order

Description

Returns a re-ordered object sorted by chromosome and start position. If strict=TRUE, then chromosomes must be in order specified by chrOrder. If ds is already ordered, no re-ordering is done. Therefore, checking order with isGenomeOrder, is unnecessary if order will be corrected if isGenomeOrder is FALSE.

Usage

```r
toGenomeOrder(ds, strict = TRUE)
```

Arguments

ds GenoSet or GRanges

strict logical, should chromosomes be in order specified by chrOrder?

Details

toGenomeOrder for GRanges differs from sort in that it orders by chromosome and start position only, rather than chromosome, strand, start, and width.

Value

re-ordered ds

See Also

Other "genome ordering": chrOrder, isGenomeOrder

Examples

```r
data(genoset, package="genoset")
toGenomeOrder( genoset.ds, strict=TRUE )
toGenomeOrder( genoset.ds, strict=FALSE )
toGenomeOrder( rowRanges(genoset.ds) )
```
## S4 method for signature 'GenoSet,ANY'
x[i, j, k, ...., withDimnames = TRUE,
    drop = FALSE]

## S4 replacement method for signature 'GenoSet,ANY,ANY,ANY'
x[i, j, k] <- value

Arguments

- **x** : GenoSet
- **i** : character, GRanges, logical, integer
- **j** : character, logical, integer
- **k** : character or integer
- **...** : additional subsetting args
- **withDimnames** : scalar logical, put dimnames on returned assay?
- **drop** : logical drop levels of space factor?
- **value** : incoming data for assay "k", rows "i" and cols "j"

Examples

data(genoset, package="genoset")
genoset.ds[1:5, 2:3] # first five probes and samples 2 and 3
genoset.ds[, "K"] # Sample called K
gr = GRanges(ranges = IRanges(start = seq(from = 15e6, by = 1e6, length = 7), width = 1, names = letters[8:14]), seqnames = rep("chr17", 7))
genoset.ds[gr, "K"] # sample K and probes overlapping those in rd, which overlap specified ranges on chr17
