**Introduction**

miRNA are small RNA fragments (18-23 nt long) that influence gene expression during development and cell stability. Morin et al [1], discovered isomiRs first time after sequencing human stem cells.

IsomiRs are miRNAs that vary slightly in sequence, which result from variations in the cleavage site during miRNA biogenesis (5'-trimming and 3'-trimming variants), nucleotide additions to the 3'-end of the mature miRNA (3'-addition variants) and nucleotide modifications (substitution variants)[2].

There are many tools designed for isomiR detection, however the majority are web application where user can not control the analysis. The two main command tools for isomiRs mapping are SeqBuster and sRNAbench[3]. *isomiRs* package is designed to analyze the output of SeqBuster tool or any other tool after converting to the desire format.

### 1 Citing isomiRs

If you use the package, please cite this paper [4].

### 2 Input format

The input should be the output of SeqBuster-miraligner tool (*.mirna files). It is compatible with mirTOP tool as well, which parses BAM files with alignments against miRNA precursors.

For each sample the file should have the following format:

| seq name freq mir start end mism add t5 t3 s5 s3 DB aml | seq name freq mir start end mism add t5 t3 s5 s3 DB aml |
|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| TGTAAACATCTACCAGCTGCTG | seq_100014_x23 23 hsa-miR-30b-5p 17 40 0 0 0 0 | TGTAAACATCCGACTGGAA | seq_100019_x4 4 hsa-miR-30d-5p 6 26 13TC 0 0 0 0 | CAAATTCGTATCGGGATT | seq_100049_x1 1 hsa-miR-10a-3p 63 81 0 TT 0 ata | TGGCATCTTTGACCACTGCTG | seq_100060_x1 1 hsa-miR-192-5p 25 47 8GT 0 c agt |
| TGTAAACATCCGACTGGAA | seq_100019_x4 4 hsa-miR-30e-5p 17 37 12CT 0 0 0 0 | TGTAAACATCCGACTGGAA | seq_100019_x4 4 hsa-miR-30e-5p 17 37 12CT 0 0 0 0 | CAAATTCGTATCGGGATT | seq_100049_x1 1 hsa-miR-10a-3p 63 81 0 TT 0 ata | TGGCATCTTTGACCACTGCTG | seq_100060_x1 1 hsa-miR-192-5p 25 47 8GT 0 c agt |

This is the standard output of SeqBuster-miraligner tool, but can be converted from any other tool having the mapping information on the precursors. Read more on miraligner manual

### 3 IsomirDataSeq class

This object will store all raw data from the input files and some processed information used for visualization and statistical analysis. It is a subclass of SummarizedExperiment with colData and counts methods. Beside that, the object contains raw and normalized counts from miraligner allowing to update the summarization of miRNA expression.

#### 3.1 Access data

The user can access the normalized count matrix with counts(object, norm=TRUE).

You can browse for the same miRNA or isomiRs in all samples with isoSelect method.

```r
library(isomiRs)
data(mirData)
head(isoSelect(mirData, mirna="hsa-let-7a-5p", 1000))
```

### 3.2 isomiRs annotation

IsomiR names follow this structure:

- **miRNA name**
- **type**: ref if the sequence is the same as the miRNA reference. ‘iso’ if the sequence has variations.
- **t5 tag**: indicates variations at 5’ position. The naming contains two words: ‘direction - nucleotides’, where direction can be UPPER CASE NT (changes upstream of the 5’ reference position) or LOWER CASE NT (changes downstream of the 5’ reference position). ‘0’ indicates no variation, meaning the 5’ position is the same as the reference. After ‘direction’, it follows the nucleotide/s that are added (for upstream changes) or deleted (for downstream changes).
- **t3 tag**: indicates variations at 3’ position. The naming contains two words: ‘direction - nucleotides’, where direction can be LOWER CASE NT (upstream of the 3’ reference position) or UPPER CASE NT (downstream of the 3’ reference position). ‘0’ indicates no variation, meaning the 3’ position is the same as the reference. After ‘direction’, it follows the nucleotide/s that are added (for downstream changes) or deleted (for upstream changes).
- **ad tag**: indicates nucleotide additions at 3’ position. The naming contains two words: ‘direction - nucleotides’, where direction is UPPER CASE NT (upstream of the 5’ reference position). ‘0’ indicates no variation, meaning the 3’ position has no additions. After ‘direction’, it follows the nucleotide/s that are added.
- **mm tag**: indicates nucleotide substitutions along the sequences. The naming contains three words: ‘position-nucleotideATsequence-nucleotideATreference’.
- **seed tag**: same as ‘mm’ tag, but only if the change happens between nucleotide 2 and 8.

In general nucleotides in UPPER case mean insertions respect to the reference sequence, and nucleotides in LOWER case mean deletions respect to the reference sequence.
4 Quick start

We are going to use a small RNAseq data from human frontal cortex samples [5] to give some basic examples of isomiRs analyses.

In this data set we will find two groups:

- b: 3 individuals with less than a year
- o: 3 individuals in the elderly.

```r
library(isomiRs)
data(mirData)
```

4.1 Reading input

The function `IsomirDataSeqFromFiles` needs a vector with the paths for each file and a data frame with the design experiment similar to the one used for a mRNA differential expression analysis. Row names of data frame should be the names for each sample in the same order than the list of files.

```
ids <- IsomirDataSeqFromFiles(fn_list, design=de)
```

4.2 Descriptive analysis

You can plot isomiRs expression with `isoPlot`. In this figure you will see how abundant is each type of isomiRs at different positions considering the total abundance and the total number of sequences. The `type` parameter controls what type of isomiRs to show. It can be trimming (iso5 and iso3), addition (add) or substitution (subs) changes.

```
ids <- isoCounts(mirData)
isoplot(ids, type="iso5", column = "group")
```
4.3 Count data

`isoCounts` gets the count matrix that can be used for many different downstream analyses changing the way isomiRs are collapsed. The following command will merge all isomiRs into one feature: the reference miRNA.

```r
head(counts(ids))
```

</tbody>
</table>

The normalization uses `rlog` from `DESeq2` package and allows quick integration to another analyses like heatmap,
4.4 Differential expression analysis

The isoDE uses functions from \textit{DESeq2} package. This function has parameters to create a matrix using only the reference miRNAs, all isomiRs, or some of them. This matrix and the design matrix are the inputs for DESeq2. The output will be a DESeqDataSet object, allowing to generate any plot or table explained in DESeq2 package vignette.

```r
dds <- isoDE(ids, formula="group")
library(DESeq2)
plotMA(dds)
```
You can differentiate between reference sequences and isomiRs at 5’ end with this command:

```r
dds = isoDE(ids, formula="group, ref=TRUE, iso5=TRUE)
head(results(dds, tidy=TRUE))
```

```
#  row baseMean log2FoldChange lfcSE stat pvalue
# 1 hsa-let-7a-2-3p.iso.t5:0 3.3721956 -1.8884006 0.7912017 -2.3867498 0.01699806
# 2 hsa-let-7a-2-3p.iso.t5:A 0.1684532 -1.0125876 3.0746413 -0.3293352 0.74190234
# 3 hsa-let-7a-2-3p.ref.t5:0 4.6743318 -0.4022899 0.6242767 -0.6444096 0.51930985
# 4 hsa-let-7a-3p.iso.t5:0 633.9291305 -0.1123118 0.2165499 -0.5186417 0.60401061
# 5 hsa-let-7a-3p.iso.t5:A 1.8192053 1.1303400 0.9964880 1.1343238 0.25665876
```
Alternative, for more complicated cases or if you want to control more the differential expression analysis parameters you can use directly `DESeq2` package feeding it with the output of `counts(ids)` and `colData(ids)` like this:

```r
dds = DESeqDataSetFromMatrix(counts(ids),
                              colData(ids), design = ~ group)
```

### 4.5 Supervised classification

Partial Least Squares Discriminant Analysis (PLS-DA) is a technique specifically appropriate for analysis of high dimensionality data sets and multicollinearity [6]. PLS-DA is a supervised method (i.e. makes use of class labels) with the aim to provide a dimension reduction strategy in a situation where we want to relate a binary response variable (in our case young or old status) to a set of predictor variables. Dimensionality reduction procedure is based on orthogonal transformations of the original variables (isomiRs) into a set of linearly uncorrelated latent variables (usually termed as components) such that maximizes the separation between the different classes in the first few components [7]. We used sum of squares captured by the model (R2) as a goodness of fit measure. We implemented this method using the `Discriminer` into `isoPLSDA` function. The output p-value of this function will tell about the statistical significant of the group separation using miRNA expression data. Moreover, the function `isoPLSDAplot` helps to visualize the results. It will plot the samples using the significant components (t1, t2, t3 ...) from the PLS-DA analysis and the samples distribution along the components.

```r
ids = isoCounts(ids, iso5=TRUE, minc=10, mins=6)
ids = isoNorm(ids, formula = ~ group)
pls.ids = isoPLSDA(ids, "group", nperm = 2)
df = isoPLSDAplot(pls.ids)
```

## Warning in warn Deprecated(!missing(legends), "legends"): ‘legends’ will be deprecated in future versions. Please remove it from your code
The analysis can be done again using only the most important discriminant isomiRs from the PLS-DA models based on the analysis. We used Variable Importance for the Projection (VIP) criterion to select the most important features, since takes into account the contribution of a specific predictor for both the explained variability on the response and the explained variability on the predictors.

```r
pls.ids = isoPLSDA(ids,"group", refinement = FALSE, vip = 0.8)
```
Session info
