getSNPlocs

\textit{Accessing the data stored in SNPlocs.Hsapiens.dbSNP.20111119}

\section*{Description}

The data sets stored in SNPlocs.Hsapiens.dbSNP.20111119 and how to access them.

\section*{Usage}

\begin{verbatim}
## Datasets:
data(SNPcount)
data(all_rsids)
data(ch1_snplocs)
data(ch2_snplocs)
data(ch3_snplocs)
data(ch4_snplocs)
data(ch5_snplocs)
data(ch6_snplocs)
data(ch7_snplocs)
data(ch8_snplocs)
data(ch9_snplocs)
data(ch10_snplocs)
data(ch11_snplocs)
data(ch12_snplocs)
data(ch13_snplocs)
data(ch14_snplocs)
data(ch15_snplocs)
data(ch16_snplocs)
data(ch17_snplocs)
data(ch18_snplocs)
data(ch19_snplocs)
data(ch20_snplocs)
data(ch21_snplocs)
data(ch22_snplocs)
data(chX_snplocs)
data(chY_snplocs)
data(chMT_snplocs)
\end{verbatim}
## Convenience wrappers for loading the SNP data:
getSNPcount()
getSNPlocs(seqname, as.GRanges=FALSE, caching=TRUE)

## Extract SNP information for a set of rs ids:
rsid2loc(rsids, caching=TRUE)
rsid2alleles(rsids, caching=TRUE)
rsidsToGRanges(rsids, caching=TRUE)

### Arguments

- **seqname**: The name of the sequence for which to get the SNP locations and alleles.
  If as.GRanges is FALSE, only one sequence can be specified (i.e. seqname must be a single string). If as.GRanges is TRUE, an arbitrary number of sequences can be specified (i.e. seqname can be a character vector of arbitrary length).

- **as.GRanges**: TRUE or FALSE. If TRUE, then the SNP locations and alleles are returned in a GRanges object. Otherwise (the default), they are returned in a data frame (see below).

- **caching**: Should the loaded SNPs be cached in memory for faster further retrieval but at the cost of increased memory usage?

- **rsids**: A vector of rs ids. Can be integer or character vector, with or without the "rs" prefix. NAs are not allowed.

### Details

See SNPlocs.Hsapiens.dbSNP.20111119 for general information about this package.

The SNP data are split by chromosome (1-22, X, Y, MT) i.e. the package contains one data set per chromosome, each of them being a serialized data frame with 1 row per SNP and the 2 following columns:

- **loc**: The 1-based location of the SNP relative to the first base at the 5’ end of the plus strand of the reference sequence.

- **alleles**: A raw vector with no NAs which can be converted into a character vector containing the alleles for each SNP represented by an IUPAC nucleotide ambiguity code (see ?IUPAC_CODE_MAP in the Biostrings package for more information).

Note that those data sets are not intended to be used directly but the user should instead use the getSNPcount and getSNPlocs convenience wrappers for loading the SNP data. When used with as.GRanges=FALSE (the default), getSNPlocs returns a data frame with 1 row per SNP and the 3 following columns:

- **RefSNP_id**: RefSNP ID (aka "rs id") with "rs" prefix removed. Character vector with no NAs and no duplicates.

- **alleles_as_ambig**: A character vector with no NAs containing the alleles for each SNP represented by an IUPAC nucleotide ambiguity code.

- **loc**: Same as for the 2-col serialized data frame described previously.

### Value

getSNPcount returns a named integer vector containing the number of SNPs for each sequence in the reference genome.
getSNPlocs

By default (as.GRanges=FALSE), getSNPlocs returns the 3-col data frame described above containing the SNP data for the specified chromosome. Otherwise (as.GRanges=TRUE), it returns a GRanges object with extra columns "RefSNP_id" and "alleles_as_ambig". Note that all the elements (genomic ranges) in this GRanges object have their strand set to * and that all the sequence lengths are set to NA.

rsid2loc and rsid2alleles both return a named vector (integer vector for the former, character vector for the latter) where each (name, value) pair corresponds to a supplied rs id. For both functions the name in (name, value) is the chromosome of the rs id. The value in (name, value) is the position of the rs id on the chromosome for rsid2loc, and a single IUPAC code representing the associated alleles for rsid2alleles.

rsidsToGRanges returns a GRanges object similar to the one returned by getSNPlocs (when used with as.GRanges=TRUE) and where each element corresponds to a supplied rs id.

Examples

```r
## A. BASIC USAGE
getSNPcount()

## Get the locations and alleles of all SNPs on chromosome 22:
ch22snps <- getSNPlocs("ch22")
dim(ch22snps)
colnames(ch22snps)
head(ch22snps)

## Get the locations and alleles of all SNPs on chromosomes 22 and MT
## as a GRanges object:
getSNPlocs(c("ch22", "chMT"), as.GRanges=TRUE)

## B. EXTRACT SNP INFORMATION FOR A SET OF RS IDS...

## ... and return it in a GRanges object:
myrsids <- c("rs2639606", "rs75264089", "rs73396229", "rs55871206",
             "rs10932221", "rs56219727", "rs73709730", "rs55838886",
             "rs3734153", "rs79381275", "rs1516535")
rsidsToGRanges(myrsids)

## C. INJECTION IN THE REFERENCE GENOME

library(BSgenome.Hsapiens.UCSC.hg19)
```
SNPlocs.Hsapiens.dbSNP.20111119

---

**Description**

This package contains SNP locations and alleles for Homo sapiens extracted from dbSNP Build 135.
Details

SNPs from dbSNP were filtered to keep only those satisfying the 3 following criteria:

- The SNP is a single-base substitution i.e. its type is "snp". Other types used by dbSNP are: "indel", "mixed", "microsatellite", "named-locus", "multinucleotide-polymorphism", etc... All those SNPs were dropped.
- The SNP is marked as notwithdrawn.
- A single location on the reference genome (GRCh37.p5) is reported for the SNP, and this location is on chromosomes 1-22, X, Y, MT.

SNPlocs packages always store the alleles corresponding to the plus strand, whatever the strand reported by dbSNP is (which is achieved by storing the complement of the alleles reported by dbSNP for SNPs located on the minus strand). In other words, in a SNPlocs package, all the SNPs are considered to be on the plus strand and everything is reported with respect to that strand.

Note

The source data files used for this package were created by the dbSNP Development Team at NCBI on Nov 18-19, 2011.

WARNING: The SNPs in this package are mapped to reference genome GRCh37.p5. Note that the GRCh37.p5 genome is a patched version of GRCh37 but the patch doesn’t alter chromosomes 1-22, X, Y, MT. GRCh37 itself is the same as the hg19 genome from UCSC *except* for the mitochondrion chromosome. Therefore, the SNPs in this package can be “injected” in BSgenome.Hsapiens.UCSC.hg19 and they will land at the correct location but this injection will exclude chrM (i.e. nothing will be injected in that sequence).

See http://www.ncbi.nlm.nih.gov/snp, the SNP Home at NCBI, for more information about dbSNP.

See ?injectSNPs in the BSgenome software package for more information about the SNP injection mechanism.

See http://genome.ucsc.edu/cgi-bin/hgGateway?clade=mammal&org=Human&db=hg19 for more information about the Human Feb. 2009 (GRCh37/hg19) assembly used by the UCSC Genome Browser.
