Experimental design

Charlotte Soneson University of Zurich Brixen 2016

"To call in the statistician after the experiment is done may be no more than asking him to perform a postmortem examination: he may be able to say what the experiment died of."

Sir Ronald Fisher, Indian Statistical Congress, Sankhya, around 1938

 The organization of an experiment, to ensure that the right type of data, and enough of it, is available to answer the questions of interest as clearly and efficiently as possible.

Treatment I

Treatment II

Analysis batch I / Study center I / Processing protocol I ...

Analysis batch II / Study center II / Processing protocol II ...

Ctl Ctl Ctl Ctl Ctl Ctl Ctl

What can happen with bad experimental design?

- Example: gene expression study comparing 60
 CEU and 82 ASN HapMap individuals
- 26% of the genes were found to be significantly differentially expressed (78% with less restrictive multiple testing correction)
- But: all CEU samples were processed (sometimes years) before all the ASN samples!

What can happen with bad experimental design?

- Example: gene expression study oaring 60
 CEU and 82 ASN HapMan
- 26% of the gener differentially multip' .ection)
- But: all CuU samples were processed (sometimes years) before all the ASN samples!

What can happen with bad experimental design?

78% differentially expressed

96% differentially expressed

"Batch effect correction" won't work here

p-values from test comparing CEU and ASN, after controlling for the processing year

What could be a good experimental design?

- Process all samples at the same time (not always feasible)
- Minimize confounding as much as possible through
 - blocking
 - randomization
- The batch effect will still be there, but with an appropriate design we can account for it!

Non-confounded design

Non-confounded design

Accounting for batch effects

- In statistical modeling, batch effects can be included as covariates (additional predictors) in the model.
- For exploratory analysis, we often attempt to "eliminate" or "adjust for" such unwanted variation in advance, by subtracting the estimated effect from each variable.
- Even partial confounding between batch and signal of interest can lead to bias.

 Public, processed RNA-seq data from 3 tissues, 4 studies show strong association with study

color = tissue; symbol = study (batch)

Accounting for the batch effect brings out signal of interest.

color = tissue; symbol = study (batch)

 5-subtype breast cancer microarray data processed in six batches.

(a)

(c)

 5-subtype breast cancer microarray data processed in six batches.

(d)

What if the batch variable is unknown?

- Manifests as systematic "unwanted variation" in data
- Identify using e.g.
 - control genes ("housekeeping" genes, spike-ins)
 - residuals after eliminating known signal
- Include estimated unwanted variation as covariate(s) in the statistical model
- RUV, sva packages commonly used in genomics

• No batch effect, no differentially expressed genes

No batch effect, some differentially expressed genes

 Batch effect (no confounding), some differentially expressed genes

Batch effect (no confounding), some differentially expressed genes - after correction

Batch effect adjustment vs normalization

 Batch effect adjustment goes beyond the "global" between-sample normalization methods.

Batch effect adjustment vs normalization

 Batch effect adjustment goes beyond the "global" between-sample normalization methods.

Other design issues: replication

- Replicates are **necessary** to estimate withincondition variability.
- Variability estimates are, in turn, vital for statistical testing.

Other design issues: replication

- Replicates are **necessary** to estimate withincondition variability.
- Variability estimates are, in turn, vital for statistical testing.

Other design issues: replication

- Replicates are **necessary** to estimate withincondition variability.
- Variability estimates are, in turn, vital for statistical testing.

Other design issues: sample size

- As always, it depends...
 - on what we want to do (differential gene expression, variant detection, GWAS, ...)
 - on the variability between samples (cell lines, inbred animals, patients, ...)
 - on the magnitude of the expected effect

FDR, 2 replicates/condition

FDR, 5 replicates/condition

FDR, 10 replicates/condition

Similarity between sets of DEGs, 2 replicates/condition

How many biological replicates are needed in an RNA-seq experiment and which differential expression tool should you use?

Nicholas J. Schurch^{1,6}, Pietá Schofield^{1,2,6}, Marek Gierliński^{1,2,6}, Christian Cole^{1,6}, Alexander Sherstnev^{1,6}, Vijender Singh², Nicola Wrobel³, Karim Gharbi³, Gordon G. Simpson⁴, Tom Owen-Hughes², Mark Blaxter³ and Geoffrey J. Barton^{1,2,5}

At least six replicates per condition for all experiments. At least 12 replicates per condition for experiments where identifying the majority of all DE genes is important.

And now for something completely different...

http://www.publicdomainpictures.net/view-image.php?imag

No matter how carefully you design your experiment, data can still be compromised...
