Package ‘CONFESS’

April 15, 2024

**Type**    Package  
**Title**   Cell OrderiNg by FluorEScence Signal  
**Version** 1.30.0  
**Date**    2019-09-19  
**Author** Diana LOW and Efthimios MOTAKIS  
**Maintainer** Diana LOW <lowdiana@gmail.com>  
**Description** Single Cell Fluidigm Spot Detector.  
**License** GPL-2  
**LazyData** TRUE  
**Depends** R (>= 3.3),grDevices,utils,stats,graphics  
**Imports** methods,changepoint,cluster,contrast,data.table(>= 1.9.7),ecp,EBImage,flexmix,flowCore,flowClust,flowMeans,flowMerge,flowPeaks,foreach,ggplot2,grid,limma,MASS,moments,outliers,parallel,plotrix,raster,readbitmap,reshape2,SamSPECTRAL,waveslim,wavethresh,zoo  
**biocViews** ImmunoOncology, GeneExpression,DataImport,CellBiology,Clustering,RNASeq,QualityControl,Visualization,TimeCourse,Regression,Classification  
**Collate** fluo_est.R fluo_NBE.R internal_fluo_NBE.R internal_fluo_est.R internal_DDHF.R simulator.R cases.R  
**RoxygenNote** 6.1.1  
**Encoding** UTF-8  
**VignetteBuilder** knitr  
**Suggests** BiocStyle, knitr, rmarkdown, CONFESSdata  
**NeedsCompilation** no  
**git_url** https://git.bioconductor.org/packages/CONFESS  
**git_branch** RELEASE_3_18  
**git_last_commit** 641088d  
**git_last_commit_date** 2023-10-24  
**Repository** Bioconductor 3.18  
**Date/Publication** 2024-04-15

**Description**

Adds the predicted k-mean clusters to the existing set (CV-estimated).

**Usage**

```r
addKpredictions(whole, cv, new.clusters, indices)
```

**Arguments**

- `whole`: List. The output of `Fluo_inspection()` on the original data.
- `cv`: List. The output of `Fluo_inspection()` on the cross-validated data.
- `new.clusters`: Numeric. The predicted k-mean clusters.
- `indices`: List. The index numbers of the old and the new data.
adjustFluo

Value

The new output of Fluo_inspection() with the original data where @GAPgroups has been replaced with the CV estimates and the new predictions and the @centroids with the CV-estimated centroids.

adjustFluo

Description

It performs the run effect correction and normalization of the raw fluorescence signals.

Usage

adjustFluo(data, transformation, BGmethod, maxMix, reference, prior.pi, flex.reps, flexmethod, image.type, savePlot, seed, dateIndex)

Arguments

data List. A list with the fluorescence signal information of both channels.
BGmethod Character string. The type of image background correction to be performed. One of "normexp" or "subtract".
maxMix Integer. The maximum number of components to fit into the mixture of regressions model. If maxMix=1 or if the the optimal number of the estimated components is 1, the model reduces to the classical 2-way ANOVA.
reference Numeric vector. Specifies the runs to be used as baseline (iteratively).
prior.pi Float. The prior probability to accept a component.
flex.reps Integer. The iterations of the Expectation-Maximization algorithm to estimate the flexmix model.

Value

A list with the fluorescence signals, mixture components and flexmix model estimates
**Description**

It estimates the average difference between the original and the CV estimated pseudotimes. For circular path types, the difference is defined as min(diff,max(pseudotime)-diff). For example assuming 300 cells (thus the maximum pseudotime is 300) in a circular path, two pseudotimes 1 and 300 differ only by 1 and not by 299.

**Usage**

```r
aveDiff(data, path.type, maxPseudo)
```

**Arguments**

- `data`: Numeric. A vector of pseudotimes whose first element is the originally estimated one (from the full data).
- `path.type`: Character. The input of `path.type` parameter in `pathEstimator()`.
- `maxPseudo`: Numeric. The maximum possible pseudotime.

**Value**

The average difference between the original and the CV estimated pseudotimes for a sample.

---

**Description**

It performs the run effect correction of the cell fluorescence signals by flexmix or 2-way ANOVA.

**Usage**

```r
BatchFluo(data, maxMix, reference, prior.pi, flex.reps, flexmethod, seed)
```

**Arguments**

- `data`: List. A list of transformed and adjusted fluorescence signals.
- `maxMix`: Integer. The maximum number of components to fit into the mixture of regressions model. If `maxMix`=1 or if the optimal number of the estimated components is 1, the model reduces to the classical 2-way ANOVA.
- `reference`: Numeric vector. Specifies the runs to be used as baseline (iteratively).
- `prior.pi`: Float. The prior probability to accept a component.
**BGcorrectFluo**

- **flex.reps**: Integer. The iterations of the Expectation-Maximization algorithm to estimate the flexmix model.
- **flexmethod**: Character string. A method to estimate the optimal number of flexmix components. One of "BIC", "AIC", "ICL".
- **seed**: Integer. An optional seed number for the Random Number Generator.

**Value**

A list of fluorescence signals, mixture components and flexmix model estimates

---

**BGcorrectFluo**

**Description**

It performs the background correction of cell fluorescence signals.

**Usage**

`BGcorrectFluo(data, method, old.offset, bg)`

**Arguments**

- **data**: Data matrix. A data matrix with the foreground and background raw signals from each channel.
- **method**: Character string. The type of background correction to be performed. One of "normexp" or "subtract".
- **old.offset**: Float. An offset for the background correction method.
- **bg**: Logical. If TRUE foreground - background is performed.

**Value**

The background corrected data
boxcoxMatrix

Description
A helper to run the Box Cox transformation on a data matrix of adjusted fluorescence signals.

Usage
boxcoxMatrix(data)

Arguments
data Numeric vector. The adjusted signals of one channel.

Value
The transformed data

boxcoxMatrixEst

Description
A helper to run the Box Cox transformation on a data matrix of adjusted fluorescence signals.

Usage
boxcoxMatrixEst(data)

Arguments
data Numeric vector. The adjusted signals of one channel.

Value
The transformed data
**Description**

It generates the density plots of the uncorrected and corrected cell fluorescence signals.

**Usage**

```r
boxFluo(data, transformation, reference, legends, batchnames, image.type, savePlot)
```

**Arguments**

- `data`: List. A list with the fluorescence data. Typically, the output of createFluo().
- `reference`: Integer. The run number to be used as baseline for the run correction.
- `legends`: Character vector. Puts the "uncorrected" or "corrected" legends on the signal density plots.
- `batchnames`: original run name.
- `image.type`: Character string. A triplet of IDs to characterize the type of images under study.
- `savePlot`: Character. A switch to generate the density plots.
- `transform`: Character string. The type of transformation to be performed. One of "bc" (Box-Cox), "log", "log10" or "asinh".

**Value**

The density plots of the fluorescence data

---

**Description**

It processes the case of 0 spots in both channels. It performs BF image modelling.

**Usage**

```r
caseof0s(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type)
```
Arguments

centerR  Data matrix. The location statistics of one channel.

centerG  Data matrix. The location statistics of the other channel.

origImg  Data matrix. The original BF image to be read and processed.

chaImgs  List. The channel image data (data matrices) of a sample.

minDiff  Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.

despeckle  Logical. If TRUE the BF image is despeckled.

ImgLimits  Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.

BFarea  Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.

chip.type  Character string. It specifies the type of Fluidigm chip to be analyzed.

separator  Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.

image.type  Character string. A triplet of IDs to characterize the type of images under study.

Value

A list of location estimates

Description

It processes the case of 1 spot in one channel and 0 spots in the other channel. BF image modelling is not necessarily performed.

Usage

```
caseof1R0G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, 
ImgLimits, BFarea, chip.type, separator, image.type)
```
Arguments

centerR Data matrix. The location statistics of one channel.
centerG Data matrix. The location statistics of the other channel.
origImg Data matrix. The original BF image to be read and processed.
chaImgs List. The channel image data (data matrices) of a sample.
minDiff Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
despeckle Logical. If TRUE the BF image is despeckled.
ImgLimits Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
BFarea Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
chip.type Character string. It specifies the type of Fluidigm chip to be analyzed.
separator Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
image.type Character string. A triplet of IDs to characterize the type of images under study.

Value

A list of location estimates

Description

It processes the case of 1 spot in both channels. BF image modelling is not necessarily performed. It reports possible contamination.

Usage

```
caseof1R1G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, 
            ImgLimits, BFarea, chip.type, separator, image.type, 
            show.possible.contamination)
```
Arguments

- **centerR**: Data matrix. The location statistics of one channel.
- **centerG**: Data matrix. The location statistics of the other channel.
- **origImg**: Data matrix. The original BF image to be read and processed.
- **chaImgs**: List. The channel image data (data matrices) of a sample.
- **minDiff**: Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
- **despeckle**: Logical. If TRUE the BF image is despeckled.
- **ImgLimits**: Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits), ImgLimits:(512-ImgLimits)] of the image matrix.
- **BFarea**: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
- **chip.type**: Character string. It specifies the type of Fluidigm chip to be analyzed.
- **separator**: Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
- **image.type**: Character string. A triplet of IDs to characterize the type of images under study.
- **show.possible.contamination**: Logical. If TRUE it reports all identified unmatched spots in both channels.

Value

A list of location estimates

```r
caseof1R2G
caseof1R2G
```

Description

It processes the case of 1 spot in the red channel and >1 spots in the green channel. BF image modelling is not necessarily performed. It reports possible contamination.

Usage

```r
caseof1R2G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type, show.possible.contamination)
```
Arguments

centerR  Data matrix. The location statistics of one channel.
centerG  Data matrix. The location statistics of the other channel.
origImg  Data matrix. The original BF image to be read and processed.
chaImgs  List. The channel image data (data matrices) of a sample.
minDiff  Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
despeckle Logical. If TRUE the BF image is despeckled.
ImgLimits Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
BFarea  Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
chip.type  Character string. It specifies the type of Fluidigm chip to be analyzed.
separator  Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
image.type  Character string. A triplet of IDs to characterize the type of images under study.
show.possible.contamination Logical. If TRUE it reports all identified unmatched spots in both channels.

Value

A list of location estimates

Description

It processes the case of >1 spots in the red channel and 1 spot in the green channel. BF image modelling is not necessarily performed. It reports possible contamination.

Usage

caseof2R1G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type, show.possible.contamination)
Arguments

centerR  Data matrix. The location statistics of one channel.
centerG  Data matrix. The location statistics of the other channel.
origImg  Data matrix. The original BF image to be read and processed.
chaImgs  List. The channel image data (data matrices) of a sample.
minDiff  Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
despeckle  Logical. If TRUE the BF image is despeckled.
ImgLimits  Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
BFarea  Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
chip.type  Character string. It specifies the type of Fluidigm chip to be analyzed.
separator  Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
image.type  Character string. A triplet of IDs to characterize the type of images under study.
show.possible.contamination  Logical. If TRUE it reports all identified unmatched spots in both channels.

Value

A list of location estimates

caseof2R2G  caseof2R2G

description

It processes the case of >1 spots in both channels. BF image modelling is not necessarily performed. It implies image contamination.

Usage

```r
caseof2R2G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type)
```
\textbf{Arguments}

- \textbf{centerR} Data matrix. The location statistics of one channel.
- \textbf{centerG} Data matrix. The location statistics of the other channel.
- \textbf{origImg} Data matrix. The original BF image to be read and processed.
- \textbf{chaImgs} List. The channel image data (data matrices) of a sample.
- \textbf{minDiff} Float. the mu_hat of the H0: image-to-noise ratio = log(\text{foreground_signal}) - log(\text{background_signal}) = \mu_{\text{hat}}. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
- \textbf{despeckle} Logical. If TRUE the BF image is despeckled.
- \textbf{ImgLimits} Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area \{cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)} of the image matrix.
- \textbf{BFarea} Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
- \textbf{chip.type} Character string. It specifies the type of Fluidigm chip to be analyzed.
- \textbf{separator} Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
- \textbf{image.type} Character string. A triplet of IDs to characterize the type of images under study.

\textbf{Value}

A list of location estimates

\begin{center}
\begin{tabular}{ll}
\textbf{caseof2Rs0G} & \textbf{caseof2Rs0G} \\
\end{tabular}
\end{center}

\textbf{Description}

It processes the case of >1 spots in one channel and 0 spots in the other channel. It performs BF image modelling and reports possible contamination.

\textbf{Usage}

\texttt{caseof2Rs0G(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type, show.possible.contamination)}
Arguments

centerR Data matrix. The location statistics of one channel.
centerG Data matrix. The location statistics of the other channel.
origImg Data matrix. The original BF image to be read and processed.
chaImgs List. The channel image data (data matrices) of a sample.
minDiff Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
despeckle Logical. If TRUE the BF image is despeckled.
ImgLimits Integer. It instructs the algorithm to find spots in the specified central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [cutSides:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
BFarea Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.
chip.type Character string. It specifies the type of Fluidigm chip to be analyzed.
separator Character string. Removes the Bright Field ("BF") and channel indicators (IDs) from the image file names.
image.type Character string. A triplet of IDs to characterize the type of images under study.
show.possible.contamination Logical. If TRUE it reports all identified unmatched spots in both channels.

cluster2outlier

Description

It turns one or more selected clusters to outlier clusters, i.e. clusters consisting of outlying corrected signals.

Usage

cluster2outlier(data, out.cluster)

Arguments

data List. The output of Fluo_inspection().

out.cluster Numeric vector. The cluster number(s) to be turned into outlier clusters.

Value

A list of corrected fluorescence signal estimates with the selected clusters turned into outlier clusters.

Examples

### here we (erroneously) assume that cluster 1 is an outlier and we flag it so below
step3.withoutliers <- cluster2outlier(step3, out.cluster=1)

### the outlier samples can be removed by FluoSelection_byRun()
step3.withoutliers <- FluoSelection_byRun(step3.withoutliers, other=which(step3.withoutliers$GAPgroups[,1]!=-999))
**contrastFluo**

**contrastFluo**

**Description**

It estimates the contrasts comparisons across runs and runs*component in each channel.

**Usage**

`contrastFluo(data, channel, legends)`

**Arguments**

- **data**
  - List. A list with the fluorescence signal information of both channels. Typically, the output of `adjustFluo()`.

- **channel**
  - Character string. An identifier for the channel to be analyzed.

**Value**

A list with the fluorescence signals, mixture components, flexmix model estimates and contrast results.

---

**cpoints**

**Description**

It performs the change-point analysis of the variance stabilized adjusted fluorescence signals.

**Usage**

`cpoints(data, thresh, cmethod, sig.level, Q, path.type, seed)`

**Arguments**

- **data**
  - List. A list of adjusted fluorescence signals in both channels. Typically, the output of `transformFluo()`.

- **thresh**
  - Integer. The minimum number of values for a cluster re-estimated by the change-point analysis.

- **cmethod**
  - Character string. The change point method to be used. It can be one of "ECP", (non-parametric) "manualECP" (non-parametric with user-defined number of change-points) or "PELT" (Pruned Exact Linear Time; parametric).

- **sig.level**
  - Float. The significance level below which we do not reject a change point.

- **Q**
  - Integer. The number of change-points to be kept if CPmethod = "manualECP".
path.type
Character vector. A user-defined vector that characterizes the cell progression dynamics. The first element can be either "circular" or "A2Z" or "other". If "circular" the path progression is assumed to exhibit a circle-like behavior. If "A2Z" the path is assumed to have a well-defined start and a well-defined end point (e.g. a linear progression). If "other" the progression is assumed to be arbitrary without an obvious directionality.

seed
Integer. An optional seed number for the Random Number Generator.

Value
A list with the adjusted fluorescence signals and their change-points

Description
It performs the change-point analysis of the variance stabilized adjusted fluorescence signals by PELT.

Usage
cpPELT(data, sig.level, thresh, seed)

Arguments
data
List. A list of adjusted fluorescence signals in both channels. Typically, the output of transformFluo().
sig.level
Float. The significance level below which we do not reject a change point.
thresh
Integer. The minimum number of values for a cluster re-estimated by the change-point analysis.
seed
Integer. An optional seed number for the Random Number Generator.

Value
A list of change-points and the associated change-point clusters
createFluo

Description
The data format creator function for the signal normalization step.

Usage
createFluo(data, dateIndex = c(), from.file = FALSE, separator = " ")

Arguments
data
Data matrix. The output data matrix of LocationMatrix().
dateIndex
a date index to be used for storing the output files. It is either transferred from LocationMatrix() or it is generated here for the first time (e.g. if image analysis was not run by CONFESS or if the analysis has been repeated many times).
from.file
Logical. If TRUE the data is read from a file whose format should be the same to the output of LocationMatrix(). Default is FALSE.
separator
Character string. It separates the run ID from the Well ID in the image filenames (the «separator1» of readFiles()). It is also used here to enable the user perform the analysis independently of the previous step (cell recognition via imaging). Default is " ".

Value
A list of reformed data to be used in subsequent analysis: index: The sample indices. RGexprs: the foreground (columns 1 and 3) and background (columns 2 and 4) signals of each channel that have been estimated by spotEstimator() and filtered in LocationMatrix(). samples: the sample IDs. batch: a matrix of the run IDs. The first column contains the original run IDs. The second column is the converted original IDs into numeric values (to be used in the statistical modeling step of Fluo_adjustment()). size: the estimated cell size. image.type: the image type IDs as defined in readFiles(). The parameter is kept in order to enable the user to use this function independently of the image analysis step. dateIndex: a date index to be used for storing the output files. It is either transferred from LocationMatrix() or it is generated here for the first time (e.g. if image analysis was not run by CONFESS or if the analysis has been repeated many times).

Examples
step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", package = "CONFESS"),separator=" ")
cutpointsEstimator

Description
A helper that estimates the change-points by various methods.

Usage
cutpointsEstimator(data, thresh, cmethod, sig.level, Q, seed)

Arguments
- data: List. A list of adjusted fluorescence signals for both channels.
- thresh: Integer. The minimum number of values for a cluster re-estimated by the change-point analysis.
- cmethod: Character string. The change point method to be used. It can be one of "ECP", (non-parametric) "manualECP" (non-parametric with user-defined number of change-points) or "PELT" (Pruned Exact Linear Time; parametric).
- sig.level: Float. The significance level below which we do not reject a change point.
- Q: Integer. The number of change-points to be kept if CPmethod = "manualECP".
- seed: Integer. An optional seed number for the Random Number Generator.

Value
The sorted transformed signal differences (path) and the associated change-points

CVsampler

Description
It samples a data subset for the cross-validation analysis.

Usage
CVsampler(data, f)

Arguments
- data: List. The output of Fluo_inspection() or Fluo_modeling(). It requires existence of the @GAPgroups slot.
- f: Float. The percentage of samples that are used in the CV analysis (the rest is re-estimated).
**DDHFfit**

**Value**
An index with the data that will remain in the analysis.

**Description**
An internal function to produce the DDHFmv clustering and other model estimates.

**Usage**
```
DDHFfit(data, den.method, savePlot)
```

**Arguments**
- `data` List. A list of fluorescence signals with their change-points and clusters.
- `den.method` Character string. A method to perform the denoising. One of "wavelets", "splines" or "lregr" (for linear regression).
- `savePlot` Character string. The directory to store the plots.

**Value**
The DDHFmv clusters and model estimates

---

**DDHFinput**

**Description**
It sorts the fluorescence signals of both channels data for DDHF.

**Usage**
```
DDHFinput(data, ms)
```

**Arguments**
- `data` Data matrix. A data matrix of fluorescence signals.
- `ms` Data matrix. A matrix of estimated cluster centroids.

**Value**
The sorted fluorescence signals
**ddhft.np.2**

**Description**

The original DDHF function (Motakis et al, 2006).

**Usage**

\[ \text{ddhft.np.2(data)} \]

**Arguments**

- **data**
  
  Numeric vector. A vector of data exhibiting monotonically increasing mean-variance relationship. The data will be transformed.

**Value**

The DDHF transformed data

---

**defineLocClusters**

**Description**

It performs quality check on the estimated location of spotEstimator() in order to flag possible outliers. The flagging is done both visually and statistically using the Grubbs test.

**Usage**

\[ \text{defineLocClusters(LocData, dims = rep(512, 2), out.method = "interactive.clustering", subset = c(), separator = ",", savePlot = "screen")} \]

**Arguments**

- **LocData**
  
  The table of the location estimates obtained by spotEstimator().

- **dims**
  
  Numeric vector. The dimensions of the image data. Default is rep(512,2).

- **out.method**
  
  Character string. The method by which to flag outliers: "interactive.clustering" or "interactive.manual" or "manual". Default is "interactive.clustering". The interactive options work through interactive plots: "interactive.clustering" enables the user to highlight the outliers via co-centric circles in the plot while "interactive.manual" asks the user to click on the plot to highlight the outliers (to confirm & finalize the picks in each plot the user has to select the "stop"
defineLocClusters

command (Windows) or press the right click in Linux/Mac. Note that 'interactive.clustering' works when one has more than or equal to 15 samples IN EACH CATEGORY (Run/Well combination). The "manual" option simply gives back the original table of location estimates with the last column being a series of "confidence". The outliers should be manually annotated by inserting "outlier" in the appropriate rows of the last column.

subset List. It allows the user to run the algorithm for a subset of data (run ids and wells). Default c() using all data. Otherwise put the run IDs and the wells (left and/or right) in a list, e.g. list(c("1772-115-xxx","1772-115-yyy","left").

separator Character string. It refers to «separator1» parameter described in readFiles() that separates the run ID from the Well ID in the original image (converted) file names. Default is "_".

savePlot Character string. Directory to store the plots if out.method = manual. Its value can be an existing directory or "screen" that prints the plot only on the screen. Default is the current working directory, getwd().

Details

The outlier locations will be re-estimated by BF image modelling or adjusted as the 2-dimensional median of all non-outlying locations.

Value

A list of components summarizing the location estimates and their quality control statistics: Results: The table of the location estimates from spotEstimator() with an extra "QCgroup" labelled column that flags the samples either by "confidence" or by "outlier" (the locations that have been selected as outliers from the interactive plots). If out.method = "manual" the column includes a series of "confidence" entries. The outliers should be manually labelled. BFdata: the outlier estimates of spotEstimator(). They are kept here for processing in the second spotEstimator() step. See spotEstimator() for more details. Processed.Files: the samples that have been processed by spotEstimator(). Also kept from the first spotEstimator() step. They will be processed in the second spotEstimator() step. Outlier.indices: a vector of outlier sample indices. They are generated from the flagging of the outliers via interactive plots. They have to be manually specified if out.method = "manual". Medians: the 2-dimensional medians by run ID and wellID sets. Wellsets: a matrix showing the directionality of the well IDs. BFarea: the size of the pseudospot. image.type: the image type IDs. dateIndex: a date index to be used in saving the output files.

Examples

library(CONFESSdata)
### set your directories
basedir<"~/"
data_path<-system.file("extdata",package="CONFESSdata")
files<readFiles(idirectory=NULL,
    BFdirectory=paste(data_path,"/BF",sep=""),
    CHdirectory=paste(data_path,"/CH",sep=""),
    separator = "_",image.type = c("BF","Green","Red"),
    bits=2^16)
#this example is run using out.method="manual" (not interactive)
clu <- defineLocClusters(LocData=estimates,out.method="manual",savePlot="screen")

denoisefun

denoisefun

Description
An internal function to run data denoising.

Usage
denoisefun(data, method)

Arguments
- data: Numeric vector. An 1-dimensional vector of pseudotime sorted transformed signal differences.
- method: Character string. A method to perform the denoising. One of "wavelets", "splines" or "lregr" (linear regression).

Value
The denoised data

denoiser

denoiser

Description
An internal function to run transformed data denoising that estimates the model residuals.

Usage
denoiser(data, method)

Arguments
- data: Data matrix. A matrix contains the sample indices, the pseudotimes, the Ch2-Ch3 transformed data and the cluster numbers.
- method: Character string. A method to perform the denoising. One of "wavelets", "splines" or "lregr" (linear regression).

Value
The denoised data and the model residuals
**Despecklefun**

**Description**

It despeckles the BF image data matrix (similar to the despeckle function of ImageJ)

**Usage**

`despecklefun(img, pix, thresh)`

**Arguments**

- `img`: Data matrix. The BF image data matrix.
- `pix`: Integer. A cutoff specifying the area to be examined for speckles.
- `thresh`: Integer. A cutoff to perform the despeckle function. If pixel signal > median object signal + thresh, the object is a speckle and the median object signal is returned.

**Value**

A despeckled image

---

**DiagnoseResiduals**

**Description**

An internal function to perform residual diagnostic tests.

**Usage**

`diagnoseResiduals(data, savePlot = "OFF")`

**Arguments**

- `data`: List. A list of fluorescence signals with their model estimates.
- `savePlot`: Character string. The directory to store the plots.

**Value**

The residual diagnostics and plots
distfromcenter

Description
It calculates the Euclidean distance between two 2-dimensional locations.

Usage
distfromcenter(data, center)

Arguments
- data: Data matrix. A 2-dimensional location.
- center: Data matrix. A second 2-dimensional location.

Value
The Euclidean distance between the two locations

doTransform

Description
It transforms the adjusted fluorescence signals of a matrix.

Usage
doTransform(data, transformation, lpar = NULL)

Arguments
- data: Data matrix. The adjusted signals of both channels.
- lpar: Float. The lambda parameter of the Box-Cox.
- transformation: Character string. The type of transformation to be performed. One of "bc" (Box-Cox), "log", "log10" or "asinh".

Value
The transformed data matrix
**estimate.new.pseudotimes**

*Description*

It estimates a unique pseudotime vector to be used for analysis with Fluo_ordering(). It is based on the cross-validation estimates for each sample and a particular method defined by pseudo.est.method parameter at Fluo_CV_modeling().

*Usage*

```r
estimate.new.pseudotimes(data)
```

*Arguments*

- `data`  
  Data matrix. The estimated pseudotimes for all samples with the original data and the CV data under two methods, i.e. "median/original" and median/null”. For details see parameter pseudo.est.method at Fluo_CV_modeling().

*Value*

It summarizes the CV-estimated pseudotimes into a single value. There are three possible methods that may produce different results. For details see parameter pseudo.est.method at Fluo_CV_modeling().

---

**estimatePath**

*Description*

The main function for automatic path estimation.

*Usage*

```r
estimatePath(data, type, start)
```

*Arguments*

- `data`  
  Data matrix. A matrix of centroids with their trigonometric function values.

- `type`  
  Character string. A user-defined value that characterizes the cell progression dynamics. It can be either "clockwise" or "anticlockwise" depending on how the path is expected to proceed.

- `start`  
  Integer. The cluster number that is assigned as the path starting point

*Value*

The sorted cluster indices (path)
Description

Example output of the SpotEstimator function

Usage

data("estimates")

Format

The format is:  List of 6 $ SpotResults : 'data.frame': 14 obs. of 14 variables: ..$ SampleID : chr [1:14] "1772-062-248_A01" "1772-062-248_A02" "1772-062-248_A03" "1772-062-248_A04" ... ..$ X : num [1:14] 259 491 262 261 258 259 189 498 194 ... ..$ Y : num [1:14] 367 219 368 369 335 367 336 278 20 ... ..$ Size : num [1:14] 31 49 19 152 141 43 59 15 49 32 ... ..$ Estimation.Type: chr [1:14] "Both.Channels" "Both.Channels" "One.Channel" "One.Channel" ... ..$ fore_Green : num [1:14] 48.4 36 26.2 45.7 32.6 ... ..$ back_Green : num [1:14] 17.2 17.3 16.6 16.9 17.1 ... ..$ fore_Red : num [1:14] 219.1 27.6 86.5 18.4 48 ... ..$ back_Red : num [1:14] 17.5 18.1 18 ... ..$ Green.StN : num [1:14] 1.442 1.01 0.626 1.389 0.889 ... ..$ Green.Pvalue : num [1:14] 6.03e-07 1.08e-03 5.55e-02 5.16e-27 4.57e-23 ... ..$ Red.StN : num [1:14] 3.5689 0.5455 2.2422 0.0256 1.3664 ... ..$ Red.Pvalue : num [1:14] 7.13e-05 3.33e-25 ... ..$ Other.Spots : chr [1:14] "0" "0" "X = 30, Y = 204 (Green) | X = 262, Y = 368 (Red)" "0" ... ..$ Outlier.Estimates:List of 14 ..$ :List of 6 .. ..$ sample : chr "1772-062-248_A01" ... ..$ centerR: num [1:2] 0 0 ... ..$ centerG: num [1:2] 0 0 ... ..$ arR : NULL ... ..$ arG : NULL ... ..$ warn : NULL ... ..$ centerR: num [1:2] 0 0 ... ..$ centerG: num [1:2] 0 0 ... ..$ arR : NULL ... ..$ arG : NULL ... ..$ warn : NULL ... ..$ centerR: num [1:2] 0 0 ... ..$ centerG: num [1:2] 0 0 ... ..$ arR : NULL ... ..$ arG : NULL ... ..$ warn : NULL ... ..$ centerR: num [1:2] 0 0 ... ..$ centerG: num [1:2] 0 0 ... ..$ arR : NULL ... ..$ arG : NULL ... ..$ warn : NULL ...
Value
description intermediates

---

**extractBFArea**

**extractBFArea**

Description

It estimates the spot or capture site location by BF image modelling.
Usage

extractBFArea(cc, img, area, BFarea)

Arguments

cc: Data matrix. An estimated spot center.
img: Data matrix. The matrix of image data from a channel.
area: Data matrix. The bright (spot) coordinates around the spot center.
BFarea: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.

Value

The area identified by BF image modelling

Description

Another helper to re-estimate the spot location or find the capture site location (BF image modelling).

Usage

failurecase(img, pattern.search, despeckle, ImgLimits, chip.type, separator, image.type)

Arguments

pattern.search: Integer. A cutoff to find horizontal and vertical lines on the chip.
despeckle: Logical. If TRUE, the BF image is despeckled.
ImgLimits: Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with ImgLimits = 50, it will search for spots in the central area [ImgLimits:(512-ImgLimits), ImgLimits:(512-ImgLimits)] of the image matrix.
separator: Character string. Removes the Bright Field ("BF") and channel indicators from the image file names.
image.type: Character string. A triplet of IDs to characterize the type of images under study.
origImg: Data matrix. The original BF image to be read and processed.
type: Character string. It specifies the type of Fluidigm chip to be analyzed.

Value

Location statistics and characteristic lines of BF image modelling
fclust

Description
The main flowClust function used in this application.

Usage
fclust(data, k, nstart = 1)

Arguments
data    Data matrix. A matrix of run effect and background corrected fluorescence signals in both channels.
k       Integer. The maximum number of clusters to be generated.
nstart  Integer. A flowClust parameter specifying the number of random sets to be chosen for the clustering estimation.

Value
The flowClust results

files

Description
Example output of readFiles with file definition and locations

Usage
data("files")

Format
Examples

data(files)

filled.contour3    filled.contour3

Description

It generates a contour plot of a channel specific spot. It is a modification by Ian Taylor of the filled.contour() to remove the key and facilitate overplotting with contour(). It has been further modified by Carey McGilliard and Bridget Ferris to allow multiple plots on one page http://wiki.cbr.washington.edu/qerm/sites/qerm/images/1/16/Filled.contour3.R We have added some extra parameters to adapt the function to our application.

Usage

filled.contour3(x = seq(0, 1, length.out = nrow(z)), y = seq(0, 1, length.out = ncol(z)), z, xlim = range(x, finite = TRUE), ylim = range(y, finite = TRUE), zlim = range(z, finite = TRUE), levels = pretty(zlim, nlevels), nlevels = 20, color.palette = cm.colors, col = color.palette(length(levels) - 1), joinedPlots, plot.title, plot.axes, key.title, key.axes, asp = NA, xaxs = "i", yaxs = "i", las = 1, axes = TRUE, frame.plot = axes, mar, ...)

Arguments

x, y, z            Numeric vectors. Some plot coordinates.

...                Other parameters of the function.

Value

A plotted spot
```markdown
---

**findPattern**

**Description**
A helper to find the characteristic straight lines of the BF image.

**Usage**

```r
findPattern(imgline, bpattern)
```

**Arguments**

- `imgline` Integer. A row or a column number of the BF image data matrix.
- `bpattern` Integer. A user-defined cutoff that specifies whether a given row or column contains a characteristic straight line.

**Value**
An estimate for the existence of a characteristic line.

---

**fixPath**

**Description**
It tests whether the path has been appropriately defined and produces an error if not.

**Usage**

```r
fixPath(data, groups)
```

**Arguments**

- `data` List. A list of fluorescence signal information for both channels.
- `groups` Numeric vector. A vector of cluster indices.

**Value**
A list with the adjusted fluorescence signals and the clusters.
```
**Description**

A helper function for flowClust analysis.

**Usage**

```r
flowclust_step1(data, k, nstart)
```

**Arguments**

- `data`: Data matrix. A matrix of run effect and background corrected fluorescence signals in both channels.
- `k`: Integer. The maximum number of clusters to be generated.
- `nstart`: Integer. A flowClust parameter specifying the number of random sets to be chosen for the clustering estimation.

**Value**

Preliminary flowClust results

---

**Description**

Another helper function for flowClust analysis.

**Usage**

```r
flowclust_step2(data)
```

**Arguments**

- `data`: Data matrix. A matrix of flowclust results from `flowclust_step1()`.

**Value**

Preliminary flowClust results
FluoInspection

Description
It generates the initial clusters, their centroids and plots the results.

Usage
FluoInspection(data, dateIndex, savePlot)

Arguments
data List. A list of fluorescence signal information for both channels.
dateIndex Character string. A date index to be used in saving the output files.
savePlot Character string. The directory to store the plots or an option to print them on the screen.

Value
A list with the adjusted fluorescence signals and the centroids

FluoSelection_byRun

Description
It accepts a subset of data to inspect their background corrected fluorescence signal characteristics. Typically, it one can input the data from a single run to identify an appropriate mixture model for run effect correction. Any other arbitrary subset of the data can also be used. For example, it can be used to keep certain samples and filter out outliers.

Usage
FluoSelection_byRun(data, batch = c(), other = c())

Arguments
data List. The output of createFluo().
batch Integer. A selected run. If it is c() then the "other" parameter should be activated. Default is 1.
other Numeric vector. It accepts the sample numbers indicating the samples to be kept for analysis, e.g. other = c(1:10, 101:110) to keep samples 1:10 and 100:110. Default is c().
Fluo_adjustment

Value

A list of reformed data to be used in subsequent analysis. It is essentially the same slots of create-Fluo() with only a subset of data included (as defined by the batch and other parameters): index: The sample indices. RGexprs: the foreground (columns 1 and 3) and background (columns 2 and 4) signals of each channel that have been estimated by spotEstimator() and filtered in Location-Matrix(). samples: the sample IDs. batch: a matrix of the run IDs. The first column contains the original run IDs. The second column is the converted original IDs into numeric values (to be used in the statistical modeling step of Fluo_adjustment()). size: the estimated cell size. image.type: the image type IDs as defined in readFiles(). The parameter is kept in order to enable the user to use this function independently of the image analysis step. dateIndex: a date index to be used for storing the output files. It is either transferred from LocationMatrix() or it is generated here for the first time (e.g. if image analysis was not run by CONFESS or if the analysis has been repeated many times).

Examples

step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", package = "CONFESS"),separator="_")
step2a <- FluoSelection_byRun(data = step1, batch = 4:5)

Fluo_adjustment

Description

A summary of the signal adjustment algorithms into a single function. It corrects the run effect (if any) and performs background adjustment for appropriately transformed data.

Usage

Fluo_adjustment(data, BGmethod = "normexp", maxMix = 3,
    single.batch.analysis = 1, transformation = "log", prior.pi = 0.1,
    flex.reps = 50, flexmethod = "BIC", savePlot = getwd(),
    seed = NULL)

Arguments

data List. The output of createFluo().
BGmethod Character string. The type of image background correction to be performed. One of "normexp" or "subtract". Default is "normexp".
maxMix Integer. The maximum number of components to fit into the mixture of regressions model. If maxMix=1 or if the optimal number of the estimated components is 1, the model reduces to the classical 2-way ANOVA. Default is 3.
single.batch.analysis

- **Integer.** The baseline run against with the run effect correction is performed. Default is 1. If 0, each run is used as baseline iteratively and the final corrected data are obtained as the average of all corrections.

transformation

- **Character string.** One of bc (Box-Cox), log, log10, asinh transforms applied to the data. Default is "log".

prior.pi

- **Float.** The prior probability to accept a component. Default is 0.1.

flex.reps

- **Integer.** The iterations of the Expectation-Maximization algorithm to estimate the flexmix model. Default is 50.

flexmethod

- **Character string.** A method to estimate the optimal number of flexmix components. One of "BIC", "AIC", "ICL". Default is "BIC".

savePlot

- **Character string.** Directory to store the plots. Its value can be an existing directory or "screen" that prints the plot only on the screen or "OFF" that does not generate a plot (suggested only during cross-validations). Default is the current working directory, getwd().

seed

- **Integer.** An optional seed number for the Random Number Generator. Note that this seed is a 'reference' value of the actual seed used in sampling. CONFESS is using various random sampling methods. Each method's actual seed is factor*seed. The factors vary across methods. Default is NULL.

Value

A list with the data description and corrected estimates over all runs by averaging (Summarized_estimates) AND for a particular "reference" run (Batch_estimates). Analytically, the components are: General index: The sample indices. samples: the sample IDs. batch: a matrix of the run IDs. The first column contains the original run IDs. The second column is the converted original IDs into numeric values (to be used in the statistical modeling step of Fluo_adjustment()). Size: the estimated cell size. RGexprs: the foreground (columns 1 and 3) and background (columns 2 and 4) signals of each channel that have been estimated by spotEstimator() and filtered in LocationMatrix(). exprs: the background corrected (only) signals of each channel. These data are fed into the flexmix model. image.type: the image type IDs as defined in readFiles(). dateIndex: the date index used. single.batch.analysis: the reference run used for run effect correction with flexmix. BGmethod: the background correction method used. maxMix: the maxMix parameter used. prior.pi: the prior.pi parameter used. flex.reps: the flex.reps parameter used. flexmethod: the flexmethod parameter used. RNG: the seed that is used to generate the results.

Summarized_estimates: corrected.exprs: the background and run effect corrected channel signals (by averaging the estimates of all runs). corrected.transformed.exprs: the background and run effect transformed corrected channel signals (by averaging the estimates of all runs). The transformation is defined in the transformation parameter (see above). allResults: the background and run effect corrected and transformed corrected channel signals (two different slots) for all runs.

Batch_estimates: it contains the analytical results for each batch in different slots. Each slot includes: corrected.exprs: the background and run effect corrected channel signals (for a run). corrected.transformed.exprs: the background and run effect transformed corrected channel signals (for a run). The transformation is defined in the transformation parameter (see above). mixes.(image.type 1): the estimated components of the flexmix model for one channel. mixes.(image.type 2): the estimated components of the flexmix model for the other channel. Batch.(image.type 1).est: the run effects of one channel. It contains the model estimates and significance P-values/FDRs. "Comp" cor-
responds to the factor of flexmix components (mixes) and "Batch" to the factor of runs. Batch.(image.type 2).est: the run effects of the other channel. It contains the model estimates and significance P-values/FDRs. "Comp" corresponds to the factor of flexmix components (mixes) and "Batch" to the factor of runs. fitted.values: the fitted values of the flexmix model for each channel. transformation: the transformation applied on the fluorescence signals (it stores the value of transformation parameter). model.residuals: the flexmix residuals for each channel. model.standardized.residuals: the flexmix standardized residuals for each channel. residual.statistics: the result of various normality tests for the residuals. lpar: the lambda parameter of the Box-Cox transformation (if used). design.(image.type 1): the design matrix of one channel. design.(image.type 2): the design matrix of the other channel. reference: the run that has been used as reference. (image.type 1).contrasts: the contrasts matrix for the differences across flexmix components and runs for one channel (only for the reference batch if any). (image.type 2).contrasts: the contrasts matrix for the differences across flexmix components and runs for the other channel (only for the reference batch if any).

Examples

step2 <- Fluo_adjustment(data=step1, flex.reps = 5, single.batch.analysis=5, savePlot="OFF")

Fluo_CV_modeling

Description

It performs the cross-validation analysis on the estimated pseudotimes and clusters of the previous step, i.e. Fluo_CV_prep() or a manually generated list based on Fluo_modeling(). This function will evaluate the change in the estimated obtained (i) from a subset of data by f-fold cross-validation where f is the percentage of the samples from a specific group (@GAPgroups) that stay in the analysis at each CV iteration, or (ii) from a subset of runs that stay in the analysis at each CV iteration. It produces informative plots for the differences in the estimates between each iteration and the original estimates. It also summarizes the CV-estimated pseudotimes into a new set of estimates.

Usage

Fluo_CV_modeling(data, B = 20, batch = 1, perc.cutoff = 0.6, q = 0.9, f = 0.9, seed.it = TRUE, pseudotime.cutoff = 20, savePlot = getwd())

Arguments

data List. The output of Fluo_CV_prep() or any other manually retrieved list with the components of Fluo_CV_prep().

B Integer. The number of cross-validation to be performed. Default is 20.

batch Numeric. A vector of runs to remain in the cross-validation. The rest are temporarily removed. The algorithm estimates the centroids of the reduced data and then calls the out-of-bag samples and re-estimates their k-mean clusters.
per.cutoff  Float. The percentage of similar CV-estimated pseudotimes for each sample. The similarity is assessed by k-means with k = 2. It serves as a cut-off to identify outlying CV-estimated pseudotimes (along with q and pseudotime.cutoff). Default is 0.6.

q  Float. The q-th quantile of the difference between the original data estimated pseudotimes and the CV-estimated pseudotimes for each sample. It serves as a cut-off to identify outlying CV-estimated pseudotimes (along with per.cutoff and pseudotime.cutoff). Default is 0.9.

f  Float. The percentage of samples from each estimated cluster (@GAPgroups) to remain in the cross-validation analysis. The rest are temporarily removed. The algorithm estimates the centroids of the reduced data and then calls the out-of-bag samples and re-estimates their k-mean clusters.

seed.it  Logical. If TRUE it performs cross-validation with the seed used in the analysis of the original data, i.e. in Fluo_CV_prep(). Default is TRUE.

pseudotime.cutoff  Integer. A user-defined value to define outlier samples (along with per.cutoff and q), i.e. samples with Pseudotime(original) - medianPseudotime(CV) > pseudotime.cutoff. Default is 20.

savePlot  Character string. Directory to store the plots of the analysis of the whole data. Its value can be an existing directory or "screen" that prints the plot only on the screen. The "OFF" option is permanently used in cross-validations). Default is the current working directory, getwd().

Value

The output of Fluo_modeling() with the original estimates and the CV-based estimated pseudotimes/clusters in different slots of component CV results. The results are categorized by run number. Each run contains the original estimates (@Original Pseudotimes), the CV-based estimates by the "median/original" method (@Reest.Pseudotimes_median/original) and the CV-based estimates by the "median/null" method (@Reest.Pseudotimes_median/null).

1. "median/original" It integrates the information of the CV and the originally estimated pseudotimes. It build kmean clusters of the B CV estimates for each sample and defines pseudotime(i) = median(pseudotime(set1,i)) where set1 is a subset of the B pseudotimes that exhibit some similarity. The similarity is assessed by k-means clustering. This subset should contain a large percentage of the B data (>per.cutoff and it's median should be lower than the q-th quantile of the average differences between the original and the CV-estimated pseudotimes across all samples. If the CV estimated pseudotimes do not satisfy the above then the algorithm returns pseudotime(i) = median(pseudotime(set2,i)) where set2 is the cluster of B pseudotimes that minimizes |median(pseudotimes(set2,i))-original.pseudotimes|.

2. "median/null" if set1 with similar pseudotimes that satisfies the above rules exists, it returns the pseudotime(i) = median(pseudotime(set1,i)). Otherwise it returns NULL, i.e. the sample CV-estimated pseudotimes are not similar and the algorithm cannot estimate reliably the pseudotime of interest.

Both solutions are then going under a final round of change-point analysis that uses the CV-estimated pseudotimes and produce the final results of Fluo_CV_modeling(). All results can be subsequently used in Fluo_ordering(). The output also includes a second component, @All.Progressions,
with the original and the CV estimated pseudotimes. This information is kept for comparison reasons and it is not used further.

Examples

```r
print("Not run because takes a long time")
#step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", 
#package = "CONFESS"),separator="-")
#steps2_4 <- Fluo_CV_prep(data=step1,init.path = "bottom/left",path.type=c("circular","clockwise"),
#single.batch.analysis = 5,flex.reps=5,altFUN="kmeans",VSmethod="DDHFmv",CPmethod="ECP",
#B.kmeans=5,CPpvalue=0.01,savePlot="OFF")
#steps2_4cv<-Fluo_CV_modeling(data=steps2_4,B=5,f=0.99,savePlot="OFF")
```

Description

It generates the data that will be used in the cross-validation analysis. Essentially, it analyzes and stores the original (full) dataset for different reference runs, seeds, starting clusters etc. It estimates the progression path automatically that is feasible only for standard paths (path.type parameter different than 'other'). For this reason this function is useful only in these cases. If otherwise, it should be omitted from the analysis and the user is should generate it manually, i.e. run Fluo_adjustment() - Fluo_modeling() series as many times as the cases to be studied with manual init.path input in Fluo_modeling().

Usage

```r
Fluo_CV_prep(data, init.path = "bottom/left", path.type = c("circular", 
"clockwise"), BGmethod = "normexp", maxMix = 3,
single.batch.analysis = 1:5, transformation = "log",
prior.pi = 0.1, flex.reps = 50, flexmethod = "BIC", areacut = 0,
fixClusters = 0, altFUN = "kmeans", k.max = 15,
VSmethod = "DDHFmv", CPmethod = "ECP", CPgroups = 5,
B.kmeans = 50, CPpvalue = 0.05, CPmingroup = 15,
savePlot = getwd(), seed = NULL)
```

Arguments

data List. The output of createFluo(), i.e. the image analysis estimates.
init.path Character vector. It defines the starting cluster of the progression path in general terms. It can be one of "top/right", "top/left", "bottom/right" or "bottom/left" indicating the cluster of interest on the 2d scatterplot of Fluo_inspection(). Default is rep("bottom/left",2), i.e. in Fucci an EM/earlyG1 like cluster.
path.type Character vector. A user-defined vector that characterizes the cell progression dynamics. The first element can be either "circular" or "A2Z" or "other". If "circular" the path progression is assumed to exhibit a circle-like behavior.
If "A2Z" the path is assumed to have a well-defined start and a well-defined end point (e.g. a linear progression). If "other" the progression is assumed to be arbitrary without an obvious directionality. Default is "circular". The second element can be either "clockwise" or "anticlockwise" depending on how the path is expected to proceed. Default is "clockwise". If the first element is "other" the second element can be omitted.

If path.type = "other", the function does not estimate a path. The cross-validation algorithm will probably fail for this kind of path.type values because it will not be able to automatically guess the progression path. It is suggested that the user runs the cross-validation manually (each time specifying the path in Fluo_modeling()), collect the data in a list similar to the one produced here and input them into Fluo_CV_modeling() to get the results.

**BGmethod**
Character string. The type of image background correction to be performed. One of "normexp" or "subtract". Default is "normexp".

**maxMix**
Integer. The maximum number of components to fit into the mixture of regressions model. If maxMix=1 or if the optimal number of the estimated components is 1, the model reduces to the classical 2-way ANOVA. Default is 3.

**single.batch.analysis**
Numeric. The baseline run(s) to perform run effect correction with flexmix. Due to iterative nature of this function it can be a series of values including 0 (averaging of run correction estimates). Default is 1:5.

**transformation**
Character string. One of bc (Box-Cox), log, log10, asinh transforms applied to the data. Default is "log".

**prior.pi**
Float. The prior probability to accept a component. Default is 0.1.

**flex.reps**
Integer. The iterations of the Expectation-Maximization algorithm to estimate the flexmix model. Default is 50.

**flexmethod**
Character string. A method to estimate the optimal number of flexmix components. One of "BIC", "AIC", "ICL". Default is "BIC".

**areacut**
Integer. The "artificial" area size (BFarea^2) of the cells estimated by BF image modelling. Default is 0, implying that the area sizes to be corrected will be estimated automatically from the data (not recommended if prior knowledge exists).

**fixClusters**
Integer. A number that defines the number of k-mean clusters to be initially generated. If 0, the function runs GAP analysis to estimate the optimal number of clusters. Default is 0.

**altFUN**
Character string. A user-defined method to generate the initial clusters. It can be one of kmeans, samSpec, fmeans,fmerge or fpeaks. Default is "kmeans".

**k.max**
Integer. This is the maximum number of clusters that can be generated by k-means (if fixClusters = 0). Default is 15.

**VSmethod**
Character string. The variance stabilization transformation method to be applied to the corrected fluorescence data prior to the change point analysis. It can be one of "log" or "DDHFmv". Default is "DDHFmv".

**CPmethod**
Character string. The change point method to be used. It can be one of "ECP", (non-parametric) "manualECP" (non-parametric with user-defined numner of
change-points) or "PELT" (Pruned Exact Linear Time; parametric). Default is ECP.

**CPgroups**

Integer. The number of change-points to be kept if CPmethod = "manualECP". Default is 5.

**B.kmeans**

Integer. The number of bootstrap samples for the calculation of the GAP statistic. Default is 50.

**CPpvalue**

Float. The significance level below which we do not reject a change point. Default is 0.05.

**CPmingroup**

Integer. The minimum number of values for a cluster re-estimated by the change-point analysis. Default is 10.

**savePlot**

Character string. Directory to store the plots of the analysis of the whole data. Its value can be an existing directory or "screen" that prints the plot only on the screen. The "OFF" option is permanently used in cross-validations). Default is the current working directory, getwd().

**seed**

Integer. An optional seed number for the Random Number Generator. Note that this seed is a ‘reference’ value of the actual seed used in sampling. CONFESS is using various random sampling methods. Each method’s actual seed is factor*seed. The factors vary across methods. Default is NULL.

**Details**

The function can also be used to generate all pseudotime/clustering results up to the function of Fluo_modeling() but the starting cluster has to be defined in general terms (see init.path parameter below). For this reason, its parameters are essentially the same to the ones defined previously at the Fluo_adjustment() - Fluo_modeling() functions.

**Value**

The results of Fluo_modeling() for difference reference runs (batches) are stored in different slots. An additional slot @init.path exists that stores the init.path parameter (its value to be used in the CV automatically).

One can directly use the run components in Fluo_ordering() to finalize the data analysis. The main purpose of this function, though, is to prepare the data for cross-validation.

**Examples**

```r
step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", package = "CONFESS"),separator="_")
steps2_4 <- Fluo_CV_prep(data=step1,init.path = "bottom/left",path.type=c("circular","clockwise"), single.batch.analysis = 5,flex.reps=5,altFUN="kmeans",VSmethod="DDHFmv",CPmethod="ECP", B.kmeans=5,CPpvalue=0.01,savePlot="OFF")
```
Description

It generates the initial cell clusters as defined by their corrected fluorescence signals. The clusters can be generated by k-means (with GAP statistic estimated number of clusters) or by flow cytometry based approaches. This function shows the number and the characteristics of the initial groups and help us inspect cells’ progression type for pathEstimator().

Usage

Fluo_inspection(data, altFUN = "kmeans", fixClusters = 0,
SAM.sigma = 200, k.max = 15, B.kmeans = 50, savePlot = getwd(),
seed = NULL)

Arguments

data List. The output of getFluo() or getFluo_byRun().
altFUN Character string. A user-defined method to generate the initial clusters. It can be one of kmeans, samSpec, fmeans,fmerge or fpeaks. Default is "kmeans".
fixClusters Integer. A number that defines the number of k-mean clusters to be initially generated. If 0, the function runs GAP analysis to estimate the optimal number of clusters. Default is 0.
SAM.sigma Integer. A value for the sigma parameter of SamSPECTRAL algorithm. Default is 200.
k.max Integer. This is the maximum number of clusters that can be generated by k-means (if fixClusters = 0). Default is 15.
B.kmeans Integer. The number of bootstrap samples for the calculation of the GAP statistic. Default is 50.
savePlot Character string. Directory to store the plots. Its value can be an existing directory or "screen" that prints the plot only on the screen or "OFF" that does not generate a plot (suggested only during cross-validations). Default is the current working directory, getwd().
seed Integer. An optional seed number for the Random Number Generator. Note that this seed is a 'reference' value of the actual seed used in sampling. CON-FESS is using various random sampling methods. Each method’s actual seed is factor*seed. The factors vary across methods. Default is NULL.

Value

A list of corrected fluorescence signal estimates and a helper plot for deciding the number of groups and the cell progression path. The output is essentially the output of getFluo() or getFluo_byRun() with the addition of the following components: GAPgroups: the groups estimated by one of the altFUN methods are depicted in the first column. The second column contains 1s for non-outlier
Fluo_modeling

signals and 2s for outlier signals (as estimated by each of the methods). clusterFUN: the altFUN method that has been used for clustering. normal.sigma: the sigma parameter of samSpec method. centroids: the 2 dimensional medians (centroids) of the estimated clusters. fixClusters: the fixClusters parameter used. Kmax: the k.means parameter used. B.kmeans: the B.kmeans parameter used.

Examples

step3 <- Fluo_inspection(data=step2.1,altFUN="kmeans",B.kmeans=5,savePlot="OFF")

Fluo_modeling

Description

It takes the initial groups and the path progression and estimates the pseudotimes of cell progression and the associated change-points (updated cell clusters).

Usage

Fluo_modeling(data, init.path, VSmethod = "DDHFmv", CPmethod = "ECP", CPgroups = 5, CPpvalue = 0.05, CPmingroup = 10, seed = NULL)

Arguments

data
init.path
VSmethod
CPmethod
CPgroups
CPpvalue
CPmingroup
seed

List. The output of pathEstimator().
Numeric vector. The cell path progression as it has been estimated by pathEstimator() or a user-defined path that can be deduced from Fluo_inspection(). The latter is suggested only when path.type = "other" in pathEstimator().
Character string. The variance stabilization transformation method to be applied to the corrected fluorescence data prior to the change point analysis. It can be one of "log" or "DDHFmv". Default is "DDHFmv".
Character string. The change point method to be used. It can be one of "ECP", (non-parametric) "manualECP" (non-parametric with user-defined number of change-points) or "PELT" (Pruned Exact Linear Time; parametric). Default is ECP.
Integer. The number of change-points to be kept if CPmethod = "manualECP". Default is 5.
Float. The significance level below which we do not reject a change point. Default is 0.05.
Integer. The minimum number of values for a cluster re-estimated by the change-point analysis. Default is 10.
Integer. An optional seed number for the Random Number Generator. Note that this seed is a ‘reference’ value of the actual seed used in sampling. CONFESS is using various random sampling methods. Each method’s actual seed is factor*seed. The factors vary across methods. Default is NULL.
Fluo_ordering

**Value**

A list of corrected fluorescence signal estimates, the pseudotimes and the cell progression clusters. The output is essentially the output of pathEstimator() with the addition of the following components: UpdatedPath: the updated progression path after re-estimation by change points and clustering. DataSorts: a matrix contains the calculated distances by orthogonal projection and the pseudotimes. DDHFupdate: it takes TRUE or FALSE to signify whether the clustering/pseudotime estimation has been updated by the re-estimation procedure. corrected.VStransformed.exprs: the background and run effect transformed corrected channel signals (by one of "log" or "DDHFmv"). The transformation is defined in the VSmethod parameter. VSmethod: the transformation that has been applied to the channel signals. Progression: it describes the estimated progression by the pseudotimes (first column) and the differences between the transformed channel signals. Updated.groups: the final clusters. CPs: the final change points detected. CPmethod: the CPmethod parameter used. CPsig: the CPpvalue parameter used. CPgroups: the CPgroups parameter used. CPmingroup: the CPmingroup parameter used.

**Examples**

```r
step4<-Fluo_modeling(data=step3.1,init.path=step3.1$Path,VSmethod="DDHFmv",
CPmethod="ECP",CPpvalue=0.01)
```

**Description**

It produces the final output table of CONFESS. It includes the Sample IDs, the Run IDs, the estimated cell areas (image analysis), the corrected fluorescence signals of both channels (run and background adjusted), the pseudotimes of cell progression, the final cell clusters and other statistics of cell progression analysis.

**Usage**

```
Fluo_ordering(data, den.method = "wavelets", savePlot = "OFF")
```

**Arguments**

- **data**
  - List. The output of Fluo_modeling().

- **den.method**
  - Character string. A method to denoise the transformed channel signal differences (used for change-point analysis). The denoising obtains the residuals that can be subjected to statistical testing (model assumptions). It is one of "splines", "wavelets" or "lregr" (linear regression). Default is "wavelets".

- **savePlot**
  - Character string. Directory to store the plots. Its value can be an existing directory or "screen" that prints the plot only on the screen or "OFF" that does not generate a plot (suggested only during cross-validations). Default is the current working directory, getwd().
Value
The list of final results in two components: Summary_results: It contains a matrix that summarizes
the findings of CONFESS. It has the index number of each sample, the sample IDs, the run IDs,
the estimated cell size, the estimated run corrected cell size, the estimated pseudotime, the log,
and if specified, DDHFmv transformed channel signals, the log or DDHFmv transformed channel
differences, the estimated clusters, the residuals and a column flagging outlier samples.
Analytical results: It contains all the components of Fluo_modeling() with the addition of: Outliers:
a vector having "normal" for non-outlier samples and "outlier" for outlier samples. The outliers
are estimated by Grubbs statistic based on their distance from the bulk of the clustered samples.
Residuals: the residuals of the fitted model for the denoising of the corrected transformed channel
differences (see parameter den.method). Residuals_diagnostics: various normality tests for the
estimated residuals.
The component of

Examples
step5<-Fluo_ordering(data=step4,savePlot="OFF")

Description
It re-estimates the location of the outlier samples

Usage
forceBF(data, cutoff, median.correction, medians, Wells, image.type)

Arguments
data List. The location statistics of both channels.
cutoff Integer. A cutoff to detect outlier locations.
median.correction Logical. If TRUE it performs median adjustment for outlier locations.
medians Data matrix. The estimated medians of non-outlier samples by run and well ID.
Wells Data matrix. The directionality of the well IDs.
image.type Character string. A triplet of IDs to characterize the type of images under study.
They refer to the ImageType part of the original image or txt file names.

Value
A list of re-estimated locations
Description

A helper for DDHF.

Usage

function.from.vector(x, y, argument.vect)

Arguments

x, y, argument.vector

Appropriate vectors for analysis.

Value

Preliminary DDHF results

GAPanalysis

Description

It performs GAP analysis using different methods. It generates the cluster numbers and an indicator of outliers.

Usage

GAPanalysis(data, fixClusters, sigma, altFUN, k.max, B.kmeans, savePlot, seed)

Arguments

data

List. A list of adjusted fluorescence signals. Typically, the output of summarizeAdjFluo().

fixClusters

Integer. A number that defines the number of k-mean clusters to be initially generated. If 0, the function runs GAP analysis to estimate the optimal number of clusters.

sigma

Integer. A value for the sigma parameter of samSPECTRAL algorithm.

altFUN

Character string. A user-defined method to generate the initial clusters. It can be one of kmeans, samSpec, fmeans,fmerge or fpeaks.

k.max

Integer. This is the maximum number of clusters that can be generated by k-means (if fixClusters = 0).
B.kmeans  
Integer. The number of bootstrap samples for GAP analysis in altFUN = kmeans.

savePlot  
Character string. The directory to store the plots or an option to print them on the screen.

seed  
Integer. An optional seed number for the Random Number Generator.

Value
A list of adjusted fluorescence signals with cluster indices and outlier indicators (the 2s in the second column of GAPgroups).

Description
It finds the spot coordinates using the spot centers or BF image modeling.

Usage
getCoordinates_stats(centerR, centerG, minDiff, chaImgs, ll, ws, estCenter)

Arguments

centerR  
Data matrix. The location statistics in one channel.

centerG  
Data matrix. The location statistics in the other channel.

minDiff  
Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.

chaImgs  
List. A list of the channel images (data matrices) of a sample.

ll  
Data matrix. An internal parameter specifying the spot center.

ws  
List. An internal parameter specifying the spot center.

estCenter  
Data matrix. The estimated spot center by BF image modelling.

Value
A series of location estimates including the channel-specific spot center and spot areas.
Description

A helper to re-estimate the spot location or find the capture site location (BF image modelling).

Usage

getCsFAIL(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFarea, chip.type, separator, image.type)

Arguments

centerR Data matrix. The location statistics of one channel.
centerG Data matrix. The location statistics of the other channel.
origImg Data matrix. The original BF image to be read and processed.
chaImgs List. A list of the channel images (data matrices) of a sample.
minDiff Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background.
despeckle Logical. If TRUE, the BF image is despeckled.
ImgLimits Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with ImgLimits = 50, it will search for spots in the central area [ImgLimits:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
BFarea Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.
chip.type Character string. It specifies the type of Fluidigm chip to be analyzed.
separator Character string. Removes the Bright Field ("BF") and channel indicators from the image file names.
image.type Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names.

Value

Location statistics under BF image modelling
getFluo

Description

It retrieves the run effect and background corrected signals.

Usage

getFluo(data, areacut = 0)

Arguments

data List. The output of the Fluo_adjustment().
areacut Integer. The "artificial" area size \((\text{BFarea}^2)\) of the cells estimated by BF image modelling. Default is 0, implying that the area sizes to be corrected will be estimated automatically from the data (not recommended if prior knowledge exists).

Value

A list of estimates to be used in subsequent analysis (the slots are the same as those of getFluo_byRun()): index: The sample indices. samples: the sample IDs. batch: a matrix of the run IDs. The first column contains the original run IDs. The second column is the converted original IDs into numeric values (to be used in the statistical modeling step of Fluo_adjustment()). Size: the estimated cell size. corrected.exprs: the background corrected channel signals (case of a single run). corrected.transformed.exprs: the background transformed corrected channel signals (case of a single run). The transformation is defined in the transformation parameter. correctedAreas: the log-transformed areas after correction and imputation. areacut: the above areacut if different from 0 or the automatically calculated one otherwise. transformation: the transformation applied on the fluorescence signals. image.type: the image type IDs as defined in readFiles(). The parameter is kept in order to enable the user to use this function independently of the image analysis step. dateIndex: the date index used. single.batch.analysis: the reference run of the run effect correction by flexmix. BGmethod: the background correction methods used. maxMix: the maxMix parameter used. prior.pi: the prior.pi parameter used. flex.reps: the flex.reps parameter used. flexmethod: the flexmethod parameter used. RNG: the seed that is used to generate the results.

Examples

step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", package = "CONFESS"), separator="_")
step2.1 <- getFluo(data=step2)
**getFluo_byRun**

### Description

It produces the background corrected data when run correction is not needed. It can be used for data coming from a single run instead of `Fluo_adjustment()`. Alternatively, this function can be used to visualize the fluorescence densities of a single batch before deciding the form of the normalization model.

### Usage

```r
getFluo_byRun(data, BGmethod = "normexp", areacut = 0,
              transformation = "log", savePlot = getwd())
```

### Arguments

- **data** List. The output of `createFluo()`.
- **BGmethod** Character string. The type of image background correction to be performed. One of "normexp" or "subtract". Default is "normexp".
- **areacut** Integer. The "artificial" area size (BFarea^2) of the cells estimated by BF image modelling. Default is 0, implying that the area sizes to be corrected will be estimated automatically from the data (not recommended if prior knowledge exists).
- **transformation** Character string. One of bc (Box-Cox), log, log10, asinh transforms applied to the data. Default is "log".
- **savePlot** Character string. Directory to store the plots. Its value can be an existing directory or "screen" that prints the plot only on the screen or "OFF" that does not generate a plot (suggested only during cross-validations). Default is the current working directory, `getwd()`.

### Value

A list of corrected signal estimates. The slots are the same to those of `getFluo()`: index: The sample indices. samples: the sample IDs. batch: a matrix of the run IDs. The first column contains the original run IDs. The second column is the converted original IDs into numeric values (to be used in the statistical modeling step of `Fluo_adjustment()`). Size: the estimated cell size. corrected.exprs: the background corrected channel signals (case of a single run). corrected.transformed.exprs: the background transformed corrected channel signals (case of a single run). The transformation is defined in the transformation parameter. correctedAreas: the log-transformed areas after correction and imputation. areacut: the above areacut if different from 0 or the automatically calculated one otherwise. transformation: the transformation applied on the fluorescence signals. image.type: the image type IDs as defined in `readFiles()`. The parameter is kept in order to enable the user to use this function independently of the image analysis step. dateIndex: the date index used. single.batch.analysis: it returns 0 because there is no run effect correction done. BGmethod: the background correction methods used. maxMix: it returns NULL because there is no flexmix run
effect correction done. prior.pi: it returns NULL because there is no flexmix run effect correction done. flex.reps: it returns NULL because there is no flexmix run effect correction done. flexmethod: it returns NULL because there is no flexmix run effect correction done. RNG: the seed that is used to generate the results.

**Examples**

```r
step1 <- createFluo(from.file=system.file("extdata", "Results_of_image_analysis.txt", package = "CONFESS"),separator="_")

### select the samples of a single run and correct them
step2a <- FluoSelection_byRun(data = step1, batch = 5)
step2.1 <- getFluo_byRun(data=step2a,savePlot="OFF")
```

---

**getSpot**

Identifies one or multiple spot(s) in the image data matrix.

**Usage**

```r
getSpot(img, rad)
```

**Arguments**

- `img`: Data matrix. The binary segmented channel image data.
- `rad`: Integer. A cut-off to separate the spots (densely clustered 1s) from small random signals (loosely clustered 1s) on the binary image.

**Value**

A matrix of bright (spot) coordinates.

---

**giveWarning**

It generates a coded message of the estimation type that is being performed.

**Usage**

```r
giveWarning(number)
```
Arguments
  number  Integer. An internally defined number that produces a message.

Value
  A coded message

---

grouplines

description
  It reconstructs the BF image characteristic lines.

Usage
  grouplines(data)

Arguments
  data  Integer. A row or a column of the BF image data matrix.

Value
  An estimate for the existence of a characteristic line

---

grubbs

description
  It performs the grubbs test for outliers.

Usage
  grubbs(data)

Arguments
  data  Numeric vector. An 1-dimensional vector of spot distances to check for outliers.

Value
  All potential outliers (indices)
**GrubbsOutliers**

**Description**

It identifies potential outliers by the Grubbs test.

**Usage**

```r
GrubbsOutliers(data, alpha)
```

**Arguments**

- `data`: Data matrix. A data matrix of fluorescence signals and model residuals.
- `alpha`: Float. A significance level for the grubbs test.

**Value**

The fluorescence signals and the potential outliers

---

**highlight.cols**

**Description**

A helper to identify the vertical BF image characteristic lines.

**Usage**

```r
highlight.cols(data, chip.type, fac)
```

**Arguments**

- `data`: Numeric. A column of the BF image data matrix.
- `chip.type`: Character string. It specifies the type of Fluidigm chip to be analyzed.
- `fac`: Float. An internally estimated factor that adjusts for different chip types.

**Value**

Estimated vertical BF characteristic lines.
### invTransform

**Description**

It back-transforms the transformed adjusted cell fluorescence signals of a matrix.

**Usage**

```r
invTransform(data, lambda, transformation)
```

**Arguments**

- `data` : Data matrix. The adjusted signals of both channels.
- `lambda` : Float. The lambda parameter of the Box-Cox.
- `transformation` : Character string. The type of transformation to be performed. One of "bc" (Box-Cox), "log", "log10" or "asinh".

**Value**

The back-transformed data matrix

---

### isotone

**Description**

The original function to perform isotone regression (Motakis et al 2006).

**Usage**

```r
isotone(x, wt = rep(1, length(x)), increasing = TRUE)
```

**Arguments**

- `x` : Numeric vector. A vector of appropriately sorted data.
- `...` : Other parameters.

**Value**

The isotone regression model estimates
**joinAreas**

**Description**

It estimates the spot area by joining the red and green bright spot location estimates.

**Usage**

```r
joinAreas(areaR, areaG, center, chaImg, areaBased, warning)
```

**Arguments**

- `areaR`: Data matrix. The bright (spot) coordinates in one channel.
- `areaG`: Data matrix. The bright (spot) coordinates in the other channel.
- `center`: Data matrix. The 2-dimensional location of the spot’s center.
- `areaBased`: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.
- `warning`: Character string. An indicator of the estimation type that has been internally performed, i.e. fluorescence-based or BF image modelling.
- `chaImg`: Data matrix. The channel binary segmented image data that are used for reference to obtain the area of interest.

**Value**

The coordinates of the spot area and its length in pixels.

---

**listSorter**

**Description**

A helper that sorts the data of a list variable.

**Usage**

```r
listSorter(data, sorter)
```

**Arguments**

- `data`: List. A list variable.
- `sorter`: Numeric vector. An appropriate sorter.

**Value**

A list of appropriately sorted data.
**lmFluo**

**Description**

It estimates the optimal number of mixtures for the flexmix model on data from multiple runs.

**Usage**

```r
lmFluo(data, batch, maxMix, reference, prior.pi, flex.reps, flexmethod, seed)
```

**Arguments**

- `data`: Numeric vector. An 1-dimensional vector of adjusted data from a single channel.
- `batch`: Integer. The run number.
- `maxMix`: Integer. The maximum number of components to fit into the mixture of regressions model.
- `reference`: Numeric vector. Specifies the runs to be used as baseline (iteratively).
- `prior.pi`: Float. The prior probability to accept a component.
- `flex.reps`: Integer. The iterations of the Expectation-Maximization algorithm to estimate the flexmix model.
- `flexmethod`: Character string. A method to estimate the optimal number of flexmix components. One of "BIC", "AIC", "ICL".
- `seed`: Integer. An optional seed number for the Random Number Generator.

**Value**

The flexmix mixture components and other statistics

---

**LocationMatrix**

**Description**

It generates the final cell location and fluorescence signal estimates and summarizes the quality control statistics.

**Usage**

```r
LocationMatrix(data, filter.by = matrix(c("FDR", "Out.Index", 0.005, "confidence"), ncol = 2), report.by.signif = "max")
```
### Arguments

**data**
Data matrix. The matrix of the location and fluorescence signal estimates after two rounds (maximum) of spotEstimator().

**filter.by**
Data matrix. A series of filtering criteria and cut-offs that specify which samples are KEPT for further analysis (see vignette). By default it flags by FDR (alpha = 0.005) and outlier index (keeps only the 'confident' estimates).

**report.by.signif**
Character string. It returns the pre-defined channel-specific signal-to-noise ratio and test statistics for each sample. If "min", the algorithm only reports the P-values/FDRs and signal-to-noise of the channel with the minimum signal-to-noise ratio. If "max", the algorithm only reports the P-values/FDRs and signal-to-noise of the channel with the maximum signal-to-noise ratio. Default is "max".

### Value

List. The first component is a data matrix of the final table of estimates. The main body of this table has been generated by spotEstimator(). It summarizes the location, the raw fluorescence signal estimates (foreground and background) and the quality control statistics. It keeps only the signal-to-noise ratio and the associated P-value/FDR of a predefined channel (see parameter report.by.signif). The last column ("Cells") consists of 1s for the samples that pass the filtering step (filter.by) and are used for further analysis. The rest of the samples are assigned 0s. The user should always inspect them along with the images to obtain the final list of samples to be used for further analysis. The second component is the date index for storing the output files. It is transferred to the next step.

### Examples

```r
### the results matrix (column 'Cells') indicates three empty capture chambers
### (thus not only outliers were associated with the absense of a cell!)
Results <- LocationMatrix(data=estimates.2,
                           filter.by = matrix(c("FDR","Out.Index",0.005,"confidence"),nrow=2))
```

---

### mean_signal

**mean_signal**

A helper to simulate the spot signal.

**Usage**

```r
mean_signal(data, noise.level)
```

**Arguments**

**data**
Numeric vector. An 1-dimensional vector of spot signals.

**noise.level**
Float. The noise level of the image.
measureB

Description
It estimates the background signal for an image.

Usage
measureB(img, area, iter, BFarea)

Arguments
- **img**: Data matrix. The matrix of image data from a channel.
- **area**: Data matrix. The bright (spot) coordinates around the spot center.
- **iter**: Integer. A number of iterations (pseudo-spots) to be summarized.
- **BFarea**: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.

Value
The background image estimates

measureF

Description
It estimates the foreground signal for an identified spot or for a predefined area within the capture site.

Usage
measureF(img, area, BFarea)

Arguments
- **img**: Data matrix. The matrix of image data from a channel.
- **area**: Data matrix. The bright (spot) coordinates around the spot center.
- **BFarea**: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.

Value
The foreground (spot) signal estimates
Description

Multiple plot function.

Usage

```r
multiplot(..., plotlist = NULL, file, cols = 1, layout = NULL)
```

Details

- `ggplot` objects can be passed in ..., or to `plotlist` (as a list of `ggplot` objects)
- `cols`: Number of columns in layout
- `layout`: A matrix specifying the layout. If present, ‘cols’ is ignored.
- If the layout is something like matrix(c(1,2,3,3), nrow=2, byrow=TRUE), then plot 1 will go in the upper left, 2 will go in the upper right, and 3 will go all the way across the bottom.

Value

- ggplot2 `multiplot`

Description

A helper to test whether the foreground signal is statistically higher than the background.

Usage

```r
myt(data, minDiff)
```

Arguments

- `data`: Numeric vector. The 1-dimensinal signal of log(foreground) - log(background).
- `minDiff`: Float. The `mu_hat` of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background.

Value

- A test P-value
**orderFluo**

**Description**

It sorts the adjusted (and transformed) fluorescence signals according to the path progression.

**Usage**

```r
orderFluo(data, path.type, updater = FALSE)
```

**Arguments**

- `data` List. A list of adjusted fluorescence signals.
- `updater` Logical. An indicator of the estimation stage. If FALSE the initial groups are analyzed, otherwise the change-point based groups are analyzed.
- `path.start` Integer. A cluster number indicating the starting cluster that algorithm should use to build the path. The cluster numbers refer to the plot generated by Fluo_inspection(). Default is 1. If `path.type` = "circular" the number does not matter. If `path.type` = "A2Z" the user should inspect the Fluo_inspection() plot to detect the beginning of the path. If `path.type` = "other", the function will not estimate a path. The user has to manually insert the path progression (the cluster numbers) in Fluo_modeling().

**Value**

A list with the adjusted fluorescence signals, the centroids, the clusters and the pseudotimes

---

**path.initiator**

**Description**

It finds the cluster that initiates the progression path.

**Usage**

```r
path.initiator(data, where)
```

**Arguments**

- `data` List. The output of Fluo_inspection().
- `where` Character. One of "random", "bottom/left", "bottom/right", "top/left", "top/right" that specify the starting point of the progression path.
**pathEstimator**

Value

A starting point for the progression path

---

**Description**

It reads the generated groups of Fluo_inspection() and estimates the path cell progression given a user-defined expected pattern. It can also join some of the groups into a single one (manual selection is required).

**Usage**

```r
pathEstimator(data, path.start = 1, path.type = c("circular", "clockwise"), joinedGroups = NULL)
```

**Arguments**

- **data** List. The output of Fluo_inspection().
- **path.start** Integer. A cluster number indicating the starting cluster that algorithm should use to build the path. The cluster numbers refer to the plot generated by Fluo_inspection(). Default is 1. If path.type = "circular" the number does not matter. If path.type = "A2Z" the user should inspect the Fluo_inspection() plot to detect the beginning of the path. If path.type = "other", the function will not estimate a path. The user has to manually insert the path progression (the cluster numbers) in Fluo_modeling().
- **path.type** Character vector. A user-defined vector that characterizes the cell progression dynamics. The first element can be either "circular" or "A2Z" or "other". If "circular" the path progression is assumed to exhibit a circle-like behavior. If "A2Z" the path is assumed to have a well-defined start and a well-defined end point (e.g. a linear progression). If "other" the progression is assumed to be arbitrary without an obvious directionality. Default is "circular". The second element can be either "clockwise" or "anticlockwise" depending on how the path is expected to proceed. Default is "clockwise". If the first element is "other" the second element can be omitted.
- **joinedGroups** List. A list of cluster numbers to join. E.g. list(c(2,4)) joins cluster 2 and 4 as depicted in the Fluo_inspection() plot. Alternatively, list(c(2,4),c(1,6)) joins cluster 2 and 4 and clusters 1 and 6 as depicted in the Fluo_inspection() plot. Each list entry should contain 2 groups. Default is NULL.
Value
The list of adjusted signal estimates, a progression path and the defined path type. The output is essentially the output of Fluo_inspection() with the addition of the following components: Path: the estimated path (visualized in the Fluo_Inspection() helper plot). path.type: the path.type that has been used to estimate the path.

Examples
step3.1 <- pathEstimator(step3,path.start=6,path.type=c("circular","clockwise"))

Description
A helper that updates the path sorted clusters after re-estimation by change-point analysis.

Usage
pathUpdater(data, path)

Arguments
data Data matrix. A matrix of centroids with their path progression indices.
path Numeric vector. The path progression indices.

Value
The sorted cluster indices (path)

Description
It generates the plotted results.

Usage
plotImages(number, origImg, chaImg, binChaImg, stats, pix, log.transform, minDiff, sample, image.type)
Arguments

number Integer. An index number that regulates the fluorescence estimation procedure.
origImg Data matrix. The original BF image to be read and processed.
chaImgs List. A list of the channel images (data matrices) of a sample.
binChaImgs List. A list of binary segmented channel image data.
stats List. A series of foreground and background statistics.
pix List. A list of bright spot coordinates in the channels.
log.transform Logical. If TRUE the image data are plotted in the log scale.
minDiff Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
sample Character string. The sample ID.
image.type Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names.

Value

the plotted results and statistics of the signal-to-noise ratio

Description

adapted from plot_clusgap from phyloseq.

Usage

plot_clusgap(clusgap, title = "Gap Statistic results")

Value

plot gap stats
**predict.kmeans**

**Description**
Takes a training sample and predicts the k-mean clusters of a new dataset (minimizing the Euclidean distance).

**Usage**

```r
## S3 method for class 'kmeans'
predict(data, centroid)
```

**Arguments**
- `data`: Data matrix. A 2-dimensional matrix of corrected fluorescence signals that are clustered by k-means.
- `centroid`: Data matrix. A 2-dimensional matrix of the k-means centroids.

**Value**
The predicted k-mean clusters.

**processImg**

**Description**
Denoises the image data to be used for spot location estimation.

**Usage**

```r
processImg(img, denoise)
```

**Arguments**
- `img`: Data matrix. The matrix of image data from a channel.
- `denoise`: Logical. If TRUE the channel image is denoised with 2-dimensional la8, universal and hard thresholding.

**Value**
A denoised image
**project**

- **Description**
  
  A helper to estimate the pseudotimes by orthogonal projection.

- **Usage**
  
  ```r
  project(data, centers)
  ```

- **Arguments**
  
  - `data`: Data matrix. The fluorescence signals of a particular cluster in both channels.
  - `centers`: Numeric vector. A vector of the 2-dimensional cluster centroids.

- **Value**
  
  The pseudotimes and cell progression

---

**readChaImg**

- **Description**
  
  It reads and processes the channel image data

- **Usage**
  
  ```r
  readChaImg(imgNames, denoise)
  ```

- **Arguments**
  
  - `denoise`: Logical. If TRUE the channel image is denoised with 2-dimesnional la8, universal and hard thresholding.
  - `imgName`: Character string. The file name of the images.

- **Value**
  
  A list of channel image estimates
Description

Reads the image data that are going to be analyzed. It converts the images into txt files. The images should be in .C01 (high resolution) or .BMP, or .JPG or .PNG format. The file names should be of the form:

Usage

readFiles(iDirectory, BFdirectory, CHdirectory, separator = " ",
    image.type = c("BF", "Red", "Green"), bits = 2^16)

Arguments

iDirectory Character string. The directory where all images are stored. The images should be in the same format. Available choices are: C01, BMP, JPEG and PNG. The function recognizes the format automatically. If omitted, the function assumes that the txt data already exist at the predefined folders.

BFdirectory Character string. The directory to store the .txt converted Bright Field images.

CHdirectory Character string. The directory to store the .txt converted channel (e.g. Red/Green) images

separator Character string. This is the «separator2» parameter that removes the Bright Field ("BF") and channel indicators (IDs) from the image file names. Default is " ".

image.type Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names. Default is c("BF","Red","Green").

bits Numeric. The image bits. It is used to unnormalize the C01 signals from readCellomics(). It does not affect the signals of other image types. Default is 2^16.

Details

"RunID(separator1)WellID(separator2)ImageType.ImageFormat

For example in "1772-062-248_A01@BF.C01", RunID = 1772-062-248", separator1 = ", WellID = A01, separator2 = @ ImageType = BF, ImageFormat = C01. The function expects to see both Bright Field and channel images. It will store them in different directories. It will return a list of the respective .txt file names. Note that separator1 and separator2 CAN BE the same character (e.g. ", ").

If the images have been already converted, then the txt files should be stored in the above form with ImageFormat = txt.

readFiles() will take the minimum overlapping sets. Converted images not present in any of the channels or the Bright Field list will be reported and discarded.
Value

A list with the following components: BF: the files names of the Bright Field converted data matrices. CH1: the files names of the converted data matrices of one channel. CH2: the files names of the converted data matrices of the other channel. separator: the separator being used. image.type: the image type IDs. dateIndex: a date index to be used in saving the output files.

Examples

library(CONFESSdata)

### set your directories

basedir<~/

data_path<-system.file("extdata","package="CONFESSdata")

## to read txt files

files<-readFiles(iDirectory=NULL,
    BFdirectory=paste(data_path,"/BF",sep=""),
    CHdirectory=paste(data_path,"/CH",sep=""),
    separator = ".",image.type = c("BF","Green","Red"),
    bits=2^16)

## to convert from BMP/JPEG images

#write_dir<~"~/converted_images/"
#files<-readFiles(iDirectory=data_path,
#    BFdirectory=paste(write_dir,"/BF",sep=""),
#    CHdirectory=paste(write_dir,"/CH",sep=""),
#    separator = ".",image.type = c("BF","Green","Red"),
#    bits=2^16)

Description

It reads and processes the original BF image.

Usage

readOriImg(imgName, despeckle, pix, thresh, separator, image.type)

Arguments

imgName Character string. The file name of the image.

despeckle Logical. If TRUE the BF image is despeckled.

pix Integer. A cutoff specifying the size of the area to search for speckles.

thresh Integer. A cutoff to perform the despeckle function. If pixel signal > median object signal + thresh, the object is a speckle and the median object signal is returned.
**reestimate.pseudos.byCV**

(separator) Character string. Removes the Bright Field ("BF") and channel indicators from the image file names.

(image.type) Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names.

**Value**

A list of BF image estimates

**Description**

It estimates a new pseudotime for each sample based on its cross-validation estimates.

**Usage**

```r
reestimate.pseudos.byCV(data, diff.quantile, perc.cutoff, pseudotime.cutoff)
```

**Arguments**

- **data** Numeric. A vector of estimated pseudotimes for one sample. The first value corresponds to the estimate of the whole data. The second value is the difference between the estimate of the original data and the median of the CV-estimated pseudotimes and it is used as a dissimilarity measure. The rest of the values are the CV estimated pseudotimes themselves.

- **diff.quantile** Float. The qth quantile of the distribution of the difference between the original and the CV-estimated pseudotimes. The q parameter is defined in Fluo_CV_modeling().

- **perc.cutoff** Float. The percentage of CV-estimated pseudotimes that are similar (clustered together by k-means)

- **pseudotime.cutoff** Integer. A user-defined value to define outlier samples, i.e. samples with Pseudotime(original) - medianPseudotime(CV) > pseudotime.cutoff.

**Value**

It summarizes the CV-estimated pseudotimes into a single value. There are three possible methods that may produce different results. For details see parameter pseudo.est.method at Fluo_CV().
refineMixes

Description

An helper internal function to generate the results of flexmix.

Usage

refineMixes(data, batch, model, seed)

Arguments

data Numeric vector. The background corrected fluorescence signals of a single channel.
batch Integer. The run number.
model Model. The output of getModel() from flexmix.
seed Integer. An optional seed number for the Random Number Generator.

Value

The flexmix mixture components

Results

Description

Example output from LocationMatrix

Usage

data("Results")

Format

levels "0.000360562783835169": 13 7 14 11 9 12 8 1 5 10 ...

<tr>
<td>signal.from.matrix</td>
<td>A helper to simulate spots in a image.</td>
</tr>
</tbody>
</table>

### Usage

#### revDDHFinput

```r
revDDHFinput(data, hft)
```

#### Arguments

- **data**: Numeric Data matrix. A data matrix of DDHF transformed data.

#### Value

- The reverted data

## Value

Some values of interest
**significantSignal**

**Description**

It tests whether the foreground signal is statistically higher than the background.

**Usage**

```r
significantSignal(centerR, centerG, minDiff, chaImgs)
```

**Arguments**

- `centerR` Data matrix. The location statistics of one channel.
- `centerG` Data matrix. The location statistics of the other channel.
- `minDiff` Float. the mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
- `chaImgs` List. A list of the channel images (data matrices) of a sample.

**Value**

P-values and test statistics for both channels

---

**simcells**

**Description**

The main function to simulate spots of various numbers, sizes, signals in one or multiple images of a given dimension.

**Usage**

```r
simcells(channels = 2, spots.per.image = c(1, 1),
         one.location = c(50, 50), image.dimension = rep(100, 2),
         signal.level = list(700, 700), noise.level = c(200, 200),
         spot.size = list(30, 30), agreement.number = 1)
```
sortCentroids

Arguments

channels
Integer. The number of channels for each sample. Default is 2.

spots.per.image
Numeric vector. The number of spots in each image (channel). The length of
the vector equals to the number of channels. Default is one spot per channel.

one.location
Numeric vector. The central location of the matched spots across the channels
(in pixel) coordinates. Default is (X,Y) = (50,50).

image.dimension
Numeric vector. The image dimension (in pixels). Default is 100 x 100.

signal.level
List. The lambda parameter of the Poisson distribution that generates the true
spot (pixel) signals. The list has as many components (length) as the number of
channels. The number of elements of each component equals to the number of
spots in each particular channel. Default is list(700,700).

noise.level
Numeric vector. The sigma parameter of the Normal distribution that generates
the image noise level. The length of the vector equals to the number of channels.
Default is c(200,200).

spot.size
List. The size of each spot on each channel (in pixels). The list has as many
components (length) as the number of channels. The number of elements of each
component equals to the number of spots in each particular channel. Default is
list(30,30).

agreement.number
Integer. It defines how many spot pairs are matched, i.e. they are located in
the same coordinates across channels. These reflect true cells. Default is 1
 corresponding to a single-cell case study.

Value

The image(s) with the generated spot(s). It consists of the data matrices and the location of the spot
centers.

Examples

r<-simcells(channels = 2, spots.per.image = c(2, 3), one.location = c(50, 50),
image.dimension = rep(200, 2), signal.level = list(c(1000, 1000), c(1000, 700, 300)),
oise.level = c(100, 100), spot.size = list(c(81, 100), c(26, 29, 50)), agreement.number = 1)
r<-simcells(channels = 2, spots.per.image = c(0, 0), image.dimension = rep(200, 2),
signal.level = list(c(),c()), noise.level = c(0, 0), spot.size = list(c(), c()))

sortCentroids

Description

A helper function to sort the centroids.
sortCentroids(data, type)

Arguments

data: Data matrix. A matrix of centroids with their trigonometric function values.
type: Character string. A user-defined value that characterizes the cell progression dynamics. It can be either "clockwise" or "anticlockwise" depending on how the path is expected to proceed.

Value

A matrix of sorted centroids

spot.simulator(location, size, average.signal, dimension)

Arguments

location: Numeric vector. A vector of 2d coordinates for the spot center.
size: Integer. The number of pixels the spot consists of.
average.signal: Float. The parameter of the poisson distribution to generate the
dimension: Numeric vector. The image dimensions.

Value

The image with the generated spot(s)
### SpotbyStrLines

**Description**

It estimates the spot location using the BF image modeling parameters.

**Usage**

`SpotbyStrLines(binImg, pattern.search, stats)`

**Arguments**

- `binImg`: List. The binary segmented image data in each channel.
- `pattern.search`: Integer. A cutoff to find horizontal and vertical lines on the chip.
- `stats`: List. The estimated parameters of the BF image modelling.

**Value**

A series of spot location estimates

---

### spotCenter

**Description**

It estimates a series of spot statistics on each channel.

**Usage**

`spotCenter(img, foregroundCut, howbig, ImgLimits)`

**Arguments**

- `img`: Data matrix. The channel image data.
- `foregroundCut`: Numeric vector. The binary segmentation image analysis cutoffs for normalized image data. Pixels with normalized signals higher than the cutoff belong to foreground.
- `howbig`: Integer. An user defined value of the minimum expected spot size.
- `ImgLimits`: a cutoff that determines where the spot is supposed to be found.

**Value**

A list of spot coordinate estimates
Description

It estimates the spot location statistics by fluorescence signal in each channel. Then, it integrates the channel-specific data into a single estimate.

Usage

```r
spotCoords(centerR, centerG, origImg, chaImgs, minDiff, despeckle, ImgLimits, BFArea, chip.type, separator, image.type, show.possible.contamination)
```

Arguments

- **centerR**: Data matrix. The location statistics of one channel.
- **centerG**: Data matrix. The location statistics of the other channel.
- **origImg**: Data matrix. The original BF image to be read and processed.
- **chaImgs**: List. A list of the red and green channel images (data matrices) of a sample.
- **minDiff**: Float. The mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.
- **despeckle**: Logical. If TRUE, the BF image is despeckled.
- **ImgLimits**: Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with ImgLimits = 50, it will search for spots in the central area [ImgLimits:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
- **BFArea**: Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated.
- **separator**: Character string. Removes the Bright Field ("BF") and channel indicators from the image file names.
- **image.type**: Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names.
- **show.possible.contamination**: Logical. If TRUE it reports all identified unmatched spots in both channels.
- **chip.type**: Character string. It specifies the type of Fluidigm chip to be analyzed.

Value

Location statistics under fluorescence-based estimation.
Description

The main function to produce the raw fluorescence signal estimation results by analysis of the Fluidigm images.

Usage

spotEstimator(files, correctionAlgorithm, subset = c(),
foregroundCut = seq(0.5, 0.7, 0.02), denoise = FALSE,
despeckle = FALSE, chip.type = "medium/large", cutSides = 0,
BFarea = 7, log.transform = TRUE, minDiff = 0.5,
show.possible.contamination = TRUE, cutoff = 50, QCdata = 0,
median.correction = TRUE, savePlot = getwd())

Arguments

files Character string. The file names to be read and analyzed. This is the output of readFiles()
correctionAlgorithm Logical. Its value specifies the estimation stage. If FALSE, the function processes all data using the standard operations of spotCoords(), i.e. case detection and fluorescence signal estimation. This is the first estimation stage. If TRUE, the function processes the BF image modeling estimates of outlier images obtained by defineLocClusters(). The BF image modeling is internally applied during the first stage. Note that correctionAlgorithm = TRUE is strictly used in the second (outliers adjustment/correction) stage of the process.
subset Numeric vector. It can be a series sample index numbers (a subset) that specifies the samples to be analyzed. The index numbers are obtained from readFiles() (the position of the sample in each listed vector). By default subset = c(). The parameter is mainly used in the second estimation stage where spotEstimator() processes the outlier images (the index numbers
foregroundCut Numeric vector. The binary segmentation image analysis cutoffs for normalized image data. Pixels with normalized signals higher than the cutoff belong to foreground. Default is seq(0.5,0.7,0.02).
denoise Logical. If TRUE it denoises the channel images with la8, universal, hard. Default is FALSE.
despeckle Logical. If TRUE the bf image is despeckled in the ImageJ fashion. Default is FALSE.
chip.type Character string. It specifies the type of Fluidigm chip to be analyzed. Default is "medium/large". The alternative option is "small".
cutSides Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with cutSides = 50, spotEstimator() will search for spots in the central area [cutSides:(512-cutSides),cutSides:(512-cutSides)] of the image matrix. Default is 0.

BFarea Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image. Default is 7.

log.transform Logical. If TRUE the image data are plotted in the log scale. Default is TRUE

minDiff Float. The mu_hat of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.

show.possible.contamination Logical. If TRUE it reports all identified unmatched spots in both channels. Default is TRUE.

cutoff Integer. A cutoff of the distance between the estimated spot location of an outlier sample (X, Y) and the median location of all non-outliers of the same run and well set (medX,medY), i.e. (X-medX, Y-medY). An outlier sample can either have a fluorescence-based location (X, Y) or a BF-based location (X*, Y*) or both. It is re-adjusted as follows: (1) if min(X-medX, Y-medY) > cutoff and min(X*-medX, Y*-medY) > cutoff, the sample’s location is set to (medX, medY); (2) if min(X*-medX, Y*-medY) <= cutoff, the sample’s location is set to (X*, Y*); (3) if min(X-medX, Y-medY) <= cutoff and min(X*-medX, Y*-medY) > cutoff, the algorithm can either produce the solution of (1) or the solution of (2) depending on the value of median.correction parameter below. By default cutoff = 50.

QCdata List. The output of defineLocClusters().

correction Logical. If TRUE, the algorithm re-adjusts the location of the outlier sample as the median of all non-outliers of the same run and well ID (if necessary).

savePlot Character string. Directory to store the plots. Its value can be an existing directory or "screen" that prints the plot only on the screen. Default is the current working directory, getwd().

Details

Triplets of images of the same sample are sequentially considered to estimate the channel-specific fluorescence signals (if detectable) or perform BF image modeling. The main result of this function is a table of location and fluorescence estimates for each sample.

Value

A list of the following components: SpotResults: the matrix of the location and fluorescence signal estimates. It contains the index number of each sample, the X,Y coordinates of the spot center, the spot size, the type of estimation that have been performed (fluorescence based indicating the channels in which the spot has been found or BF image modelling based), the fluorescence foreground
and background signals of each channel, the signal-to-noise ratio (logForeground - logBackground) for each channel, the associated P-value of significance of the signal-to-noise ratio and a column indicating the coordinates of other spots that are not matched in both images. Existence of such spots (values that are different from 0) indicate contaminated image or highly noisy images or images with other artefacts. If correctionAlgorithm=TRUE (second spotEstimator() step), there is an extra column generated indicating outlier samples (see the QCgroup column in defineLocClusters()). Outlier.Estimates: The estimates obtained from BF modeling (if necessary to be obtained). These are alternative location estimates that will be used if the original estimates of the SpotResults table are flagged as outliers. Processed.Files: the samples that have been processed by spotEstimator(). BFarea: the pseudospot size. image.type: the image type IDs. dateIndex: a date index to be used in saving the output files.

Examples

```r
## set your directories
basedir<"~/
#data_path<-system.file("extdata",package="CONFESSdata")
#files<-readFiles(iDirectory=NULL,
  # BFdirectory=paste(data_path,"/BF",sep=""),
  # CHdirectory=paste(data_path,"/CH",sep=""),
  # separator = ",",image.type = c("BF","Green","Red"),
  # bits=2^16)

## an example where the second image produces a clear outlier!
#estimates <- spotEstimator(files=files,subset=1:3,foregroundCut=seq(0.6,0.76,0.02),
  # correctionAlgorithm=FALSE,savePlot="screen")
```

---

**SpotStats**

**spotStats**

**Description**

It produces a table of estimated spot locations and fluorescence signals accompanied by informative plots. It can process the results of either spotCoords() for fluorescence-based estimation or forceBF() for BF image modelling estimation.

**Usage**

```r
SpotStats(img, chaImgs, binChaImgs, center, other.spots, BFcoords, BFarea,
  log.transform, warning, minDiff, separator, image.type)
```

**Arguments**

- **img**: Data matrix. The original data of the BF image to be read and processed.
- **chaImgs**: List. A list of the channel images (data matrices) of a sample.
- **binChaImgs**: List. A list of binary segmented channel image data.
- **center**: Data matrix. The 2-dimensional location of the spot’s representative center.
BFcoords

List. A list of statistics describing the C1 chip line patterns (for BF image modelling).

BFarea

Integer. Defines a rectangular pseudo-spot size whose fluorescence will be estimated. This is mainly used in BF image modeling where a fluorescence spot could not be originally detected. The value of this parameter is also used as a cut-off to find matched spots across channel of the same sample image.

log.transform

Logical. If TRUE the image data are plotted in the log scale.

warning

Character string. An indicator of the estimation type that has been internally performed, i.e. fluorescence-based or BF image modelling.

minDiff

Float. The mean of the H0: image-to-noise ratio = log(foreground_signal) - log(background_signal) = mu_hat. Rejection of H0 implies that the identified spot is brighter than background. Default is 0.5.

separator

Character string. Removes the Bright Field ("BF") and channel indicators from the image file names (see «separator2» in readFiles()).

image.type

Character string. A triplet of IDs to characterize the type of images under study. They refer to the ImageType part of the original image or txt file names.

Value

A table of location and fluorescence estimated with accompanied plots

**straightColLines**

**Description**
It identifies the vertical BF image characteristic lines.

**Usage**

\[ \text{straightColLines}(\text{img}, \text{pattern.search}, \text{cut} = \text{seq}(0.3, 1.5, 0.02), \text{ImgLimits}, \text{chip.type}) \]

**Arguments**
- **img**: Data matrix. The BF image data matrix.
- **pattern.search**: Integer. A cutoff to find horizontal and vertical lines on the chip.
- **cut**: Integer. A normalized signal cutoff above which a pixel is considered as foreground.
- **ImgLimits**: Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area \([\text{ImgLimits} : (512 - \text{ImgLimits}), \text{ImgLimits} : (512 - \text{ImgLimits})]\) of the image matrix.
- **chip.type**: Character string. It specifies the type of Fluidigm chip to be analyzed.

**Value**
Estimated vertical BF characteristic lines.

**straightRowLines**

**Description**
It identifies the horizontal BF image characteristic lines.

**Usage**

\[ \text{straightRowLines}({\text{colData}}, \text{pattern.search}, \text{ImgLimits}) \]

**Arguments**
- **colData**: List. The data to be analyzed.
- **pattern.search**: Integer. A cutoff to find horizontal and vertical lines on the chip.
- **ImgLimits**: Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area \([\text{ImgLimits} : (512 - \text{ImgLimits}), \text{ImgLimits} : (512 - \text{ImgLimits})]\) of the image matrix.
subsetAnalysis

Description
It reads a subset of the original file names.

Usage
subsetAnalysis(files, sub)

Arguments
- files List. A list of all BF and channel file names.
- sub Character string. A vector of the file names to be read.

Value
A list of files to be analyzed

summarizeAdjFluo

Description
A wrapper of the functions used for run effect and background correction. It gives the corrected, transformed corrected and mixture groups of each baseline run.

Usage
summarizeAdjFluo(data, transformation, BGmethod, maxMix, reference, prior.pi, flex.reps, flexmethod, image.type, savePlot, seed)
transformFluo

Arguments

data List. A list with the fluorescence signal information of both channels.
BMethod Character string. The type of image background correction to be performed. One of "normexp" or "subtract".
maxMix Integer. The maximum number of components to fit into the mixture of regressions model. If maxMix=1 or if the optimal number of the estimated components is 1, the model reduces to the classical 2-way ANOVA.
reference Numeric vector. Specifies the runs to be used as baseline (iteratively).
prior.pi Float. The prior probability to accept a component.
flex.reps Integer. The iterations of the Expectation-Maximization algorithm to estimate the flexmix model.
flexmethod Character string. A method to estimate the optimal number of flexmix components. One of "BIC", "AIC", "ICL".
image.type Character string. A triplet of IDs to characterize the type of images under study.
savePlot Character string. The directory to store the plots or an option to print them on the screen.
seed Integer. An optional seed number for the Random Number Generator.
transform Character string. The type of transformation to be performed. One of "bc" (Box-Cox), "log", "log10" or "asinh".

Value

A list with the adjusted fluorescence signals

Description

It performs the variance stabilizing transformation of the fluorescence signals.

Usage

transformFluo(data, method)

Arguments

data List. A list of adjusted fluorescence signals in both channels. Typically, the output of orderFluo().
method Character string. The variance stabilizing method. One of "DDHFmv" or "log".

Value

A list with the adjusted fluorescence signals and the transformed adjusted fluorescence signals
trigofun

Description
It computes the sin, cos and tan trigonometric functions for a number of points (2-dimensional fluorescence centroids) relative to the start of the axes.

Usage
trigofun(data)

Arguments
data Data matrix. A matrix of fluorescence centroids.

Value
The centroids and their trigonometric function values

unnormalizeC01

Description
It calculates the unnormalized signal of a normalized image. The normalization has been originally performed as \( x[i,j]/\text{bits} \) where \( x[i,j] \) is the i,j element of the signal matrix \( x \) and \( \text{bits} \) is the value of the bits.

Usage
unnormalizeC01(data, bits)

Arguments
data Data matrix. The matrix of the normalized image signals.

bits Numeric. The image bits.

Value
A matrix of unnormalized image signals
**updateCentroids**

Description

It updates the centroids of the clusters that are re-estimated by change-point analysis.

Usage

updateCentroids(data, centroidTable)

Arguments

data Data matrix. A matrix of appropriately transformed fluorescence signals.

centroidTable Data matrix. A previously estimated centroids table to be updated.

Value

The updated centroids table

**updateCentroidsPaths**

Description

It updates the path sorted clusters after re-estimation by change-point analysis.

Usage

updateCentroidsPaths(data, estimates, path.type)

Arguments

data List. A list of adjusted fluorescence signals.

estimates List. A list of sorted Ch2-Ch3 transformed fluorescence signals with their associated change-points.

path.type Character vector. A user-defined vector that characterizes the cell progression dynamics. The first element can be either "circular" or "A2Z" or "other". If "circular" the path progression is assumed to exhibit a circle-like behavior. If "A2Z" the path is assumed to have a well-defined start and a well-defined end point (e.g. a linear progression). If "other" the progression is assumed to be arbitrary without an obvious directionality.

Value

A list of adjusted fluorescence signals and the updated path after the change-point analysis
which.min.diff

Description
A helper for DDHF

Usage
which.min.diff(a, vect)

Arguments
a, vector Appropriate vectors for analysis

Value
Preliminary DDHF results

zoomInBF

Description
It estimates the chip characteristics for BF image modelling

Usage
zoomInBF(img, pattern.search, ImgLimits, chip.type)

Arguments
img Data matrix. The BF image data.
pattern.search Integer. A cutoff to find horizontal and vertical lines on the chip.
ImgLimits Integer. It instructs the algorithm to find spots in a certain central image area. For example, for a 512 x 512 image with cutSides = 50, it will search for spots in the central area [ImgLimits:(512-ImgLimits),ImgLimits:(512-ImgLimits)] of the image matrix.
chip.type Character string. It specifies the type of Fluidigm chip to be analyzed.

Value
The locations of the straight lines on the chip
