Package ‘DelayedArray’

March 3, 2022

Title A unified framework for working transparently with on-disk and in-memory array-like datasets

Description Wrapping an array-like object (typically an on-disk object) in a DelayedArray object allows one to perform common array operations on it without loading the object in memory. In order to reduce memory usage and optimize performance, operations on the object are either delayed or executed using a block processing mechanism. Note that this also works on in-memory array-like objects like DataFrame objects (typically with Rle columns), Matrix objects, ordinary arrays and, data frames.

array selection

NOTE: The tools documented in this man page are primarily intended for developers or advanced users curious about the internals of the DelayedArray package. End users typically don’t need them for their regular use of DelayedArray objects.

An array selection is just an index into an array-like object that contains the information of which array elements are selected. This index can take various forms but 3 special forms are particularly useful and extensively used throughout the DelayedArray framework: **linear index** (also referred to as L-index or Lindex), **matrix index** (also referred to as M-index or Mindex), **N-dimensional index** (also referred to as N-index or Nindex). See Details section below for more information.

Two utility functions are provided at the moment to convert back and forth between **L-indices** and **M-indices**. More will be added in the future to convert between other types of array indices.

Usage

```r
## Convert back and forth between L-indices and M-indices:
Lindex2Mindex(Lindex, dim, use.names=FALSE)
Mindex2Lindex(Mindex, dim, use.names=FALSE, as.integer=FALSE)
```

Arguments

- **Lindex**: An L-index. See Details section below.
- **Mindex**: An M-index. See Details section below.
  
  For convenience, Mindex can also be specified as an integer vector with one element per dimension in the underlying array, in which case it will be treated like a 1-row matrix.
- **dim**: An integer vector containing the dimensions of the underlying array.
  
  Note that dim can also be an integer matrix, in which case it must have one row per element in Lindex (or per row in Mindex) and one column per dimension in the underlying array.
- **use.names**: Should the names (or rownames) on the input be propagated to the output?
as.integer  Set to TRUE to force Mindex2Lindex to return the L-index as an integer vector.

Dangerous!

By default, i.e. when as.integer=FALSE, Mindex2Lindex will return the L-index either as an integer or numeric vector. It will choose the former only if it’s safe, that is, only if all the values in the L-index “fit” in the integer type. More precisely:

- If dim is not a matrix (i.e. is a vector) or if it’s a matrix with a single row: Mindex2Lindex returns an integer or numeric vector depending on whether prod(dim) is <= .Machine$integer.max (2^31 - 1) or not.
- Otherwise Mindex2Lindex returns a numeric vector.

Note that with these rules, Mindex2Lindex can return a numeric vector even if an integer vector could have been used.

Use as.integer=TRUE only in situations where you know that all the L-index values are going to “fit” in the integer type. Mindex2Lindex will return garbage if they don’t.

Details

The 3 special forms of array indices extensively used throughout the DelayedArray framework:

1. Linear index (or L-index or Lindex): A numeric vector with no NAs where each value is >= 1 and <= the length of the array-like object. When using an L-index to subset an array-like object, the returned value is a vector-like object (i.e. no dimensions) of the same length as the L-index.

Example:

```r
a <- array(101:124, 4:2)
Lindex <- c(7, 2, 24, 2)
a[Lindex]
```

2. Matrix index (or M-index or Mindex): An integer matrix with one column per dimension in the array-like object and one row per array element in the selection. No NAs. The values in each column must be >= 1 and <= the extent of the array-like object along the corresponding dimension. When using an M-index to subset an array-like object, the returned value is a vector-like object (i.e. no dimensions) of length the number of rows in the M-index.

Example:

```r
a <- array(101:124, 4:2)
Mindex <- rbind(c(3, 2, 1),
                c(2, 1, 1),
                c(4, 3, 2),
                c(2, 1, 1))
a[Mindex]
```

Note that this is the type of index returned by base::arrayInd.

3. N-dimensional (or N-index or Nindex): A list with one list element per dimension in the array-like object. Each list element must be a subscript describing the selection along the corresponding dimension of the array-like object. IMPORTANT: A NULL subscript is interpreted
as a *missing* subscript ("missing" like in `a[, ,1:2]`), that is, as a subscript that runs along the full extent of the corresponding dimension of the array-like object. This means that before an N-index can be used in a call to `[`, `[[`, `[[`, or `[[<`, the NULL list elements in it must be replaced with objects of class "name". When using an N-index to subset an array-like object, the returned value is another array-like object of dimensions the lengths of the selections along each dimensions.

Examples:

```r
a <- array(101:124, 4:2)

## Normalized N-index:

Nindex <- list(c(1, 4, 1), NULL, 1)
## Same as a[c(1, 4, 1), , 1, drop=FALSE]:
DelayedArray:::subset_by_Nindex(a, Nindex)

Nindex <- list(integer(0), NULL, 1)
## Same as a[integer(0), , 1, drop=FALSE]:
DelayedArray:::subset_by_Nindex(a, Nindex)

## Non-normalized N-index:

Nindex <- list(-3, NULL, 1)
Nindex <- DelayedArray:::normalizeNindex(Nindex, a)
## Same as a[-3, , 1, drop=FALSE]:
DelayedArray:::subset_by_Nindex(a, Nindex)

Nindex <- list(IRanges(2, 4), NULL, 1)
Nindex <- DelayedArray:::normalizeNindex(Nindex, a)
## Same as a[2:4, , 1, drop=FALSE]:
DelayedArray:::subset_by_Nindex(a, Nindex)

dimnames(a)[[1]] <- LETTERS[1:4]
Nindex <- list(c("D", "B"), NULL, 1)
Nindex <- DelayedArray:::normalizeNindex(Nindex, a)
## Same as a[c("D", "B"), , 1, drop=FALSE]:
DelayedArray:::subset_by_Nindex(a, Nindex)
```

**Value**

`Lindex2Mindex` returns an M-index.

`Mindex2Lindex` returns an L-index.

**See Also**

`arrayInd` in the `base` package.
Examples

```r
dim <- 4:2
Mindex2Lindex(c(4, 3, 1), dim)
Mindex2Lindex(c(4, 3, 2), dim)

Mindex <- rbind(c(1, 1, 1),
                c(2, 1, 1),
                c(3, 1, 1),
                c(4, 1, 1),
                c(1, 2, 1),
                c(1, 1, 2),
                c(4, 3, 2))

Mindex2Lindex(Mindex, dim)

## With a matrix of dimensions:

dims <- rbind(c(4L, 3L),
              c(5L, 3L),
              c(6L, 3L))

Mindex <- rbind(c(1, 2),
                c(1, 2),
                c(1, 2))

Mindex2Lindex(Mindex, dims)

## Sanity checks:

dim <- c(33:30, 45L, 30L)
stopifnot(Mindex2Lindex(rep(1, 6), dim) == 1)
stopifnot(Mindex2Lindex(dim, dim) == prod(dim))

stopifnot(identical(Mindex2Lindex(arrayInd(1:120, 6:4), 6:4), 1:120))
stopifnot(identical(Mindex2Lindex(arrayInd(840:1, 4:7), 4:7), 840:1))
```

Description

A grid is a partitioning of an array-like object into blocks (or viewports).

In the DelayedArray package, grids and viewports are formally represented by ArrayGrid and ArrayViewport objects, respectively.

There are two variants of ArrayGrid objects:

- RegularArrayGrid objects: for grids where all the blocks have the same geometry (except maybe for the edge blocks).
- ArbitraryArrayGrid objects: for grids where blocks don’t necessarily have the same geometry.
ArrayGrid and ArrayViewport objects are used extensively in the context of block processing of array-like objects.

Usage

```r
## Constructor functions:
RegularArrayGrid(refdim, spacings=refdim)
ArbitraryArrayGrid(tickmarks)
downsample(x, ratio=1L)
```

Arguments

- `refdim` An integer vector containing the dimensions of the reference array.
- `spacings` An integer vector specifying the grid spacing along each dimension.
- `tickmarks` A list of integer vectors, one along each dimension of the reference array, representing the tickmarks along that dimension. Each integer vector must be sorted in ascending order. NAs or negative values are not allowed.
- `x` An ArrayGrid object.
- `ratio` An integer vector specifying the ratio of the downsampling along each dimension. Can be of length 1, in which case the same ratio is used along all the dimensions.

Details

RegularArrayGrid and ArbitraryArrayGrid are concrete subclasses of ArrayGrid, which itself is a virtual class.

Note that an ArrayGrid or ArrayViewport object doesn’t store any array data, only the geometry of the grid or viewport. This makes these objects extremely light-weight, even for grids made of millions of blocks.

Value

For `RegularArrayGrid()`, a RegularArrayGrid instance.
For `ArbitraryArrayGrid()`, an ArbitraryArrayGrid instance.
For `downsample()`, an ArrayGrid object on the same reference array than `x`.

See Also

- `read_block`
- `blockApply` and family for convenient block processing of an array-like object.
- `mapToGrid` for mapping reference array positions to grid positions and vice-versa.
- `chunkGrid`
- `DelayedArray` objects.
- `array` objects in base R.
Examples

## A. ArrayGrid OBJECTS

## Create a regularly-spaced grid on top of a 3700 x 100 x 33 array:
grid1 <- RegularArrayGrid(c(3700, 100, 33), c(250, 100, 10))

## Dimensions of the reference array:
refdim(grid1)

## Number of grid elements along each dimension of the reference array:
dim(grid1)

## Total number of grid elements:
length(grid1)

## First element in the grid:
grid1[[1L]]    # same as grid1[[1L, 1L, 1L]]

## Last element in the grid:
grid1[[length(grid1)]]    # same as grid1[[15L, 1L, 4L]]

## Dimensions of the grid elements:
dims(grid1)    # one row per grid element

## Lengths of the grid elements:
lengths(grid1)    # same as rowProds(dims(grid1))
stopifnot(sum(lengths(grid1)) == prod(refdim(grid1)))

maxlength(grid1)    # does not need to compute lengths(grid1)) first
                     # so is more efficient than max(lengths(grid1))

## Create an arbitrary-spaced grid on top of a 15 x 9 matrix:
grid2 <- ArbitraryArrayGrid(list(c(2L, 7:10, 13L, 15L), c(5:6, 6L, 9L))

refdim(grid2)

dim(grid2)

c

length(grid2)

grid2[[1L]]    # same as grid2[[1L, 1L]]
grid2[[length(grid2)]]    # same as grid2[[15L, 9L]]

dims(grid2)

lengths(grid2)

array(lengths(grid2), dim(grid2))    # display the grid element lengths in
                     # an array of same shape as grid2

stopifnot(sum(lengths(grid2)) == prod(refdim(grid2)))

maxlength(grid2)    # does not need to compute lengths(grid2)) first
                     # so is more efficient than max(lengths(grid2))
stopifnot(maxlength(grid2) == max(lengths(grid2)))

## Max (i.e. highest) resolution grid:
Hgrid <- RegularArrayGrid(6:4, c(1, 1, 1))
Hgrid
dim(Hgrid)  # same as refdim(Hgrid)
stopifnot(identical(dim(Hgrid), refdim(Hgrid)))
stopifnot(all(lengths(Hgrid) == 1))

## Min (i.e. lowest) resolution grid:
Lgrid <- RegularArrayGrid(6:4, 6:4)
Lgrid
stopifnot(all(dim(Lgrid) == 1))
stopifnot(identical(dim(Lgrid[[1L]]), refdim(Lgrid)))
stopifnot(identical(dims(Lgrid), matrix(refdim(Lgrid), nrow=1)))

## B. ArrayViewport OBJECTS

## Grid elements are ArrayViewport objects:
grid1[[1L]]
stopifnot(is(grid1[[1L]], "ArrayViewport"))
grid1[[2L]]
grid1[[2L, 1L, 1L]]
grid1[[15L, 1L, 4L]]

## Construction of a standalong ArrayViewport object:
m0 <- matrix(1:30, ncol=5)
block_dim <- c(4, 3)
viewport1 <- ArrayViewport(dim(m0), IRanges(c(3, 2), width=block_dim))
viewport1
dim(viewport1)  # 'block_dim'
length(viewport1)  # number of array elements in the viewport
ranges(viewport1)

## C. GRIDS CAN BE TRANPOSED

## Use aperm() if the grid has more than 2 dimensions:
tgrid1 <- aperm(grid1)
dim(tgrid1)
refdim(tgrid1)

aperm(grid1, c(3, 1, 2))
aperm(grid1, c(1, 3, 2))
aperm(grid1, c(3, 1))  # some dimensions can be dropped
aperm(grid1, c(3, 2, 3))  # and some can be repeated

## D. DOWNSAMPLING AN ArrayGrid OBJECT

## The elements (ArrayViewport) of an ArrayGrid object can be replaced
## with bigger elements obtained by merging adjacent elements. How many
## adjacent elements to merge along each dimension is specified via the
## 'ratio' vector (one integer per dimension). We call this operation
## "downsampling. It can be seen as reducing the "resolution" of a grid
## by the specified ratio (if we think of the grid elements as pixels).

downsampling(grid2, 2)
downsampling(grid2, 3)
downsampling(grid2, 4)

## Downsampling preserves the dimensions of the reference array:
stopifnot(identical(refdim(downsampling(grid2, 2)), refdim(grid2)))
stopifnot(identical(refdim(downsampling(grid2, 3)), refdim(grid2)))
stopifnot(identical(refdim(downsampling(grid2, 4)), refdim(grid2)))

## A big enough ratio will eventually produce the coarsest possible grid
## i.e. a grid with a single grid element covering the entire reference
## array:
grid3 <- downsampling(grid2, 7)
length(grid3)
grid3[[1L]]
stopifnot(identical(dim(grid3[[1L]]), refdim(grid3)))

## Downsampling by a ratio of 1 is a no-op:
stopifnot(identical(downsampling(grid2, 1), grid2))

## Using one ratio per dimension:
downsampling(grid2, c(2, 1))

## Downsampling a max resolution grid:
refdim <- c(45, 16, 20)
grid4 <- RegularArrayGrid(refdim, c(1, 1, 1))
ratio <- c(6, 1, 3)
stopifnot(identical(
    downsampling(grid4, ratio),
    RegularArrayGrid(refdim, ratio)
))

AutoBlock-global-settings

Control the geometry of automatic blocks

Description

A family of utilities to control the automatic block size (or length) and shape.
Usage

getAutoBlockSize()
setAutoBlockSize(size=1e8)

g.setAutoBlockLength(type)

g.setAutoBlockShape()
setAutoBlockShape(shape=c("hypercube", "scale", "first-dim-grows-first", "last-dim-grows-first"))

Arguments

size The auto block size (automatic block size) in bytes. Note that, except when the type of the array data is "character" or "list", the size of a block is its length multiplied by the size of an array element. For example, a block of 500 x 1000 x 500 doubles has a length of 250 million elements and a size of 2 Gb (each double occupies 8 bytes of memory).

The auto block size is set to 100 Mb at package startup and can be reset anytime to this value by calling setAutoBlockSize() with no argument.

type A string specifying the type of the array data.

shape A string specifying the auto block shape (automatic block shape). See makeCappedVolumeBox for a description of the supported shapes.

The auto block shape is set to "hypercube" at package startup and can be reset anytime to this value by calling setAutoBlockShape() with no argument.

Details

\[ \text{block size} \neq \text{block length} \]

\[ \text{block length} = \text{number of array elements in a block} \text{ (i.e. prod(dim(block)))}. \]

\[ \text{block size} = \text{block length} \times \text{size of the individual elements in memory}. \]

For example, for an integer array, block size (in bytes) is going to be 4 x block length. For a numeric array x (i.e. type(x) == "double"), it's going to be 8 x block length.

In its current form, block processing in the DelayedArray package must decide the geometry of the blocks before starting the walk on the blocks. It does this based on several criteria. Two of them are:

- The auto block size: maximum size (in bytes) of a block once loaded in memory.
- The type() of the array (e.g. integer, double, complex, etc...)

The auto block size setting and type(x) control the maximum length of the blocks. Other criteria control their shape. So for example if you set the auto block size to 8GB, this will cap the length of the blocks to 2e9 if your DelayedArray object x is of type integer, and to 1e9 if it's of type double.

Note that this simple relationship between block size and block length assumes that blocks are loaded in memory as ordinary (a.k.a. dense) matrices or arrays. With sparse blocks, all bets are off.
But the max block length is always taken to be the auto block size divided by get_type_size(type()) whether the blocks are going to be loaded as dense or sparse arrays. If they are going to be loaded as sparse arrays, their memory footprint is very likely to be smaller than if they were loaded as dense arrays so this is safe (although probably not optimal).

It’s important to keep in mind that the auto block size setting is a simple way for the user to put a cap on the memory footprint of the blocks. Nothing more. In particular it doesn’t control the maximum amount of memory used by the block processing algorithm. Other variables can impact dramatically memory usage like parallelization (where more than one block is loaded in memory at any given time), what the algorithm is doing with the blocks (e.g. something like blockApply(x,identity) will actually load the entire array data in memory), what delayed operations are on x, etc... It would be awesome to have a way to control the maximum amount of memory used by a block processing algorithm as a whole but we don’t know how to do that.

Value

getAutoBlockSize: The current auto block size in bytes as a single numeric value.
setAutoBlockSize: The new auto block size in bytes as an invisible single numeric value.
getAutoBlockLength: The auto block length as a single integer value.
getAutoBlockShape: The current auto block shape as a single string.
setAutoBlockShape: The new auto block shape as an invisible single string.

See Also

• defaultAutoGrid and family to create automatic grids to use for block processing of array-like objects.
• blockApply and family for convenient block processing of an array-like object.
• The makeCappedVolumeBox utility to make capped volume boxes.

Examples

g AutoMapperSize()

g AutoMapperLength("double")
getAutoBlockLength("integer")
getAutoBlockLength("logical")
getAutoBlockLength("raw")

m <- matrix(runif(600), ncol=12)
setAutoBlockSize(140)
getAutoBlockLength(type(m))
defaultAutoGrid(m)
lengths(defaultAutoGrid(m))
dims(defaultAutoGrid(m))

g AutoMapperShape()

setAutoBlockShape("scale")
defaultAutoGrid(m)
lengths(defaultAutoGrid(m))
AutoGrid

Create automatic grids to use for block processing of array-like objects

Description

We provide various utility functions to create grids that can be used for block processing of array-like objects:

- `defaultAutoGrid()` is the default automatic grid maker. It creates a grid that is suitable for block processing of the array-like object passed to it.
- `rowAutoGrid()` and `colAutoGrid()` are more specialized automatic grid makers, for the 2-dimensional case. They can be used to create a grid where the blocks are made of full rows or full columns, respectively.
- `defaultSinkAutoGrid()` is a specialized version of `defaultAutoGrid()` for creating a grid that is suitable for writing to a `RealizationSink` derivative while walking on it.

Usage

defaultAutoGrid(x, block.length=NULL, chunk.grid=NULL, block.shape=NULL)

## Two specialized "automatic grid makers" for the 2-dimensional case:
rowAutoGrid(x, nrow=NULL, block.length=NULL)
colAutoGrid(x, ncol=NULL, block.length=NULL)

## Replace default automatic grid maker with user-defined one:
getAutoGridMaker()
setAutoGridMaker(GRIDMAKER="defaultAutoGrid")

## A specialized version of defaultAutoGrid() to create an automatic grid on a RealizationSink derivative:
defaultSinkAutoGrid(sink, block.length=NULL, chunk.grid=NULL)

Arguments

- `x` An array-like or matrix-like object for `defaultAutoGrid`. A matrix-like object for `rowAutoGrid` and `colAutoGrid`.
- `block.length` The length of the blocks i.e. the number of array elements per block. By default the automatic block length (returned by `getAutoBlockLength(type(x))`, or `getAutoBlockLength(type(sink))` in the case of `defaultSinkAutoGrid()`) is used. Depending on how much memory is available on your machine, you
might want to increase (or decrease) the automatic block length by adjusting
the automatic block size with setAutoBlockSize().

chunk.grid  The grid of physical chunks. By default chunkGrid(x) (or chunkGrid(sink)
in the case of defaultSinkAutoGrid()) is used.

block.shape  A string specifying the shape of the blocks. See makeCappedVolumeBox for a
description of the supported shapes. By default getAutoBlockShape() is used.

nrow  The number of rows of the blocks. The bottommost blocks might have less. See
examples below.

col  The number of columns of the blocks. The rightmost blocks might have less. See
examples below.

GRIDMAKER  The function to use as automatic grid maker, that is, the function that will be
used by blockApply() and blockReduce() to make a grid when no grid is
supplied via their grid argument. The function will be called on array-like
object x and must return an ArrayGrid object, say grid, that is compatible with
x i.e. such that refdim(grid) is identical to dim(x).

GRIDMAKER can be specified as a function or as a single string naming a function.
It can be a user-defined function or a pre-defined grid maker like defaultAutoGrid,
rowAutoGrid, or colAutoGrid.

The automatic grid maker is set to defaultAutoGrid at package startup and
can be reset anytime to this value by calling setAutoGridMaker() with no arg-

sink  A RealizationSink derivative.

Details

By default, primary block processing functions blockApply() and blockReduce() use the grid
returned by defaultAutoGrid(x) to walk on the blocks of array-like object x. This can be changed
with setAutoGridMaker().

By default sinkApply() uses the grid returned by defaultSinkAutoGrid(sink) to walk on the
viewports of RealizationSink derivative sink and write to them.

Value

defaultAutoGrid: An ArrayGrid object on reference array x. The grid elements define the blocks
that will be used to process x by block. The grid is optimal in the sense that:

1. It’s compatible with the grid of physical chunks a.k.a. chunk grid. This means that, when
the chunk grid is known (i.e. when chunkGrid(x) is not NULL or chunk.grid is supplied),
every block in the grid contains one or more full chunks. In other words, chunks never cross
block boundaries.

2. Its resolution is such that the blocks have a length that is as close as possible to (but does not
exceed) block.length. An exception is made when some chunks already have a length that
is >= block.length, in which case the returned grid is the same as the chunk grid.

Note that the returned grid is regular (i.e. is a RegularArrayGrid object) unless the chunk grid is not
regular (i.e. is an ArbitraryArrayGrid object).
**AutoGrid**

rowAutoGrid: A `RegularArrayGrid` object on reference array `x` where the grid elements define blocks made of full rows of `x`.

colAutoGrid: A `RegularArrayGrid` object on reference array `x` where the grid elements define blocks made of full columns of `x`.

defaultSinkAutoGrid: Like defaultAutoGrid except that defaultSinkAutoGrid always returns a grid with a "first-dim-grows-first" shape (note that, unlike the former, the latter has no `block.shape` argument). The advantage of using a grid with a "first-dim-grows-first" shape in the context of writing to the viewports of a `RealizationSink` derivative is that such a grid is guaranteed to work with "linear write only" realization backends. See important notes about "Cross realization backend compatibility" in `write_block` for more information.

**See Also**

- `setAutoBlockSize` and `setAutoBlockShape` to control the geometry of automatic blocks.
- `blockApply` and family for convenient block processing of an array-like object.
- `ArrayGrid` for the formal representation of grids and viewports.
- The `makeCappedVolumeBox` utility to make *capped volume boxes*.
- `chunkGrid`.
- `read_block` and `write_block`.

**Examples**

```r
## A VERSION OF sum() THAT USES BLOCK PROCESSING
block_sum <- function(a, grid) {
  sums <- lapply(grid, function(viewport) sum(read_block(a, viewport)))
  sum(unlist(sums))
}

## On an ordinary matrix:
m <- matrix(runif(600), ncol=12)
m_grid <- defaultAutoGrid(m, block.length=120)
sum1 <- block_sum(m, m_grid)
sum1

## On a DelayedArray object:
library(HDF5Array)
M <- as(m, "HDF5Array")
sum2 <- block_sum(M, m_grid)
sum2

sum3 <- block_sum(M, colAutoGrid(M, block.length=120))
sum3

sum4 <- block_sum(M, rowAutoGrid(M, block.length=80))
sum4
```
## Sanity checks:
sum0 <- sum(m)
stopifnot(identical(sum1, sum0))
stopifnot(identical(sum2, sum0))
stopifnot(identical(sum3, sum0))
stopifnot(identical(sum4, sum0))

## defaultAutoGrid()
grid <- defaultAutoGrid(m, block.length=120)
grid
as.list(grid) # turn the grid into a list of ArrayViewport objects
table(lengths(grid))
stopifnot(maxlength(grid) <= 120)

grid <- defaultAutoGrid(m, block.length=120,
                        block.shape="first-dim-grows-first")
grid
table(lengths(grid))
stopifnot(maxlength(grid) <= 120)

grid <- defaultAutoGrid(m, block.length=120,
                        block.shape="last-dim-grows-first")
grid
table(lengths(grid))
stopifnot(maxlength(grid) <= 120)

defaultAutoGrid(m, block.length=100)
defaultAutoGrid(m, block.length=75)
defaultAutoGrid(m, block.length=25)
defaultAutoGrid(m, block.length=20)
defaultAutoGrid(m, block.length=10)

## rowAutoGrid() AND colAutoGrid()

rowAutoGrid(m, nrow=10) # 5 blocks of 10 rows each
rowAutoGrid(m, nrow=15) # 3 blocks of 15 rows each plus 1 block of 5 rows
colAutoGrid(m, ncol=5) # 2 blocks of 5 cols each plus 1 block of 2 cols

## See ‘?write_block’ for an advanced example of user-implemented
## block processing using colAutoGrid() and a realization sink.

## REPLACE DEFAULT AUTOMATIC GRID MAKER WITH USER-DEFINED ONE

getAutoGridMaker()
setAutoGridMaker(function(x) colAutoGrid(x, ncol=5))
getAutoGridMaker()

blockApply(m, function(block) currentViewport())
## Reset automatic grid maker to factory settings:
setAutoGridMaker()

### Description

Bind array-like objects with an arbitrary number of dimensions along their rows (`arbind`) or columns (`acbind`).

### Usage

```r
arbind(...)  
acbind(...)  
```

### Arguments

`...`  
The array-like objects to bind.

### Value

An array-like object, typically of the same class as the input objects if they all have the same class.

### See Also

- `DelayedArray` in this package for `arbind/acbind`'ing DelayedArray objects.
- `rbind` and `cbind` in the `base` package for the corresponding operations on matrix-like objects.
- The `abind` package from CRAN.

### Examples

```r
a1 <- array(1:60, c(3, 5, 4),  
             dimnames=list(NULL, paste0("M1y", 1:5), NULL))
a2 <- array(101:240, c(7, 5, 4),  
             dimnames=list(paste0("M2x", 1:7), paste0("M2y", 1:5), NULL))
a3 <- array(10001:10100, c(5, 5, 4),  
             dimnames=list(paste0("M3x", 1:5), NULL, paste0("M3z", 1:4)))
arbind(a1, a2, a3)
```
Description
A family of convenience functions to walk on the blocks of an array-like object and process them.

Usage
## Main looping functions:
```r
blockApply(x, FUN, ..., grid=NULL, as.sparse=FALSE,
           BPPARAM=getAutoBPPARAM(), verbose=NA)
```

```r
blockReduce(FUN, x, init, ..., BREAKIF=NULL, grid=NULL, as.sparse=FALSE,
            verbose=NA)
```

## Lower-level looping functions:
```r
gridApply(grid, FUN, ..., BPPARAM=getAutoBPPARAM(), verbose=NA)
```

```r
gridReduce(FUN, grid, init, ..., BREAKIF=NULL, verbose=NA)
```

## Retrieve grid context for the current block/viewport:
```r
effectiveGrid(envir=parent.frame(2))
currentBlockId(envir=parent.frame(2))
currentViewport(envir=parent.frame(2))
```

## Get/set automatic parallel back-end:
```r
getAutoBPPARAM()
setAutoBPPARAM(BPPARAM=NULL)
```

## For testing/debugging callback functions:
```r
set_grid_context(effective_grid, current_block_id, envir=parent.frame(1))
```

Arguments
- **x**: An array-like object, typically a `DelayedArray` object or derivative.
- **FUN**: For `blockApply` and `blockReduce`, FUN is the callback function to apply to each block of data in x. More precisely, FUN will be called on each block of data in x defined by the grid used to walk on x.
  IMPORTANT: If `as.sparse` is set to FALSE, all blocks will be passed to FUN as ordinary arrays. If it's set to TRUE, they will be passed as `SparseArraySeed` objects. If it's set to NA, then `is_sparse(x)` determines how they will be passed to FUN.
  For `gridApply()` and `gridReduce()`, FUN is the callback function to apply to each **viewport** in grid.
  Beware that FUN must take at least **two** arguments for `blockReduce()` and `gridReduce()`. More precisely:
- blockReduce() will perform \( \text{init} \leftarrow \text{FUN}(\text{block}, \text{init}, \ldots) \) on each block, so \( \text{FUN} \) must take at least arguments \( \text{block} \) and \( \text{init} \).
- gridReduce() will perform \( \text{init} \leftarrow \text{FUN}(\text{viewport}, \text{init}, \ldots) \) on each viewport, so \( \text{FUN} \) must take at least arguments \( \text{viewport} \) and \( \text{init} \).

In both cases, the exact names of the two arguments doesn’t really matter. Also \( \text{FUN} \) is expected to return a value of the same type as its 2nd argument (\( \text{init} \)).

... Additional arguments passed to \( \text{FUN} \).

grid The grid used for the walk, that is, an \texttt{ArrayGrid} object that defines the blocks (or viewports) to walk on.

For blockApply() and blockReduce() the supplied grid must be compatible with the geometry of \( x \). If not specified, an automatic grid is used. By default \texttt{defaultAutoGrid(x)} is called to create an automatic grid. The \texttt{automatic grid maker} can be changed with \texttt{setAutoGridMaker()}. See ?setAutoGridMaker for more information.

as.sparse Passed to the internal calls to \texttt{read_block}. See ?read_block for more information.

BPPARAM A \texttt{NULL}, in which case blocks are processed sequentially, or a \texttt{BiocParallelParam} instance (from the \texttt{BiocParallel} package), in which case they are processed in parallel. The specific \texttt{BiocParallelParam} instance determines the parallel backend to use. See ?BiocParallelParam in the \texttt{BiocParallel} package for more information about parallel back-ends.

verbose Whether block processing progress should be displayed or not. If set to \texttt{NA} (the default), verbosity is controlled by \texttt{DelayedArray:::get_verbose_block_processing()}. Setting \texttt{verbose} to \texttt{TRUE} or \texttt{FALSE} overrides this.

init The value to pass to the first call to \( \text{FUN}(\text{block}, \text{init}) \) (or \( \text{FUN}(\text{viewport}, \text{init}) \)) when blockReduce() (or gridReduce()) starts the walk. Note that blockReduce() and gridReduce() always operate sequentially.

BREAKIF An optional callback function that detects a break condition. Must return \texttt{TRUE} or \texttt{FALSE}. At each iteration blockReduce() (and gridReduce()) will call it on the result of \( \text{init} \leftarrow \text{FUN}(\text{block}, \text{init}) \) (on the result of \( \text{init} \leftarrow \text{FUN}(\text{viewport}, \text{init}) \) for gridReduce()) and exit the walk if \( \text{BREAKIF}(\text{init}) \) returned \texttt{TRUE}.

envir Do not use (unless you know what you are doing).

effective_grid, current_block_id See Details below.

Details

effectiveGrid(), currentBlockId(), and currentViewport() return the "grid context" for the block/viewport being currently processed. By "grid context" we mean:

- The \textit{effective grid}, that is, the user-supplied grid or \texttt{defaultAutoGrid(x)} if the user didn’t supply any grid.
- The \textit{current block id} (a.k.a. block rank).
- The \textit{current viewport}, that is, the \texttt{ArrayViewport} object describing the position of the current block w.r.t. the effective grid.
Note that `effectiveGrid()`, `currentBlockId()`, and `currentViewport()` can only be called (with no arguments) from **within** the callback functions `FUN` and/or `BREAKIF` passed to `blockApply()` and family.

If you need to be able to test/debug your callback function as a standalone function, set an arbitrary `effective grid` and `current block id` by calling

```
set_grid_context(effective_grid, current_block_id)
```

**right before** calling the callback function.

**Value**

For `blockApply()` and `gridApply()`, a list with one list element per block/viewport visited.

For `blockReduce()` and `gridReduce()`, the result of the last call to `FUN`.

For `effectiveGrid()`, the grid (ArrayGrid object) being effectively used.

For `currentBlockId()`, the id (a.k.a. rank) of the current block.

For `currentViewport()`, the viewport (ArrayViewport object) of the current block.

**See Also**

- `defaultAutoGrid` and family to create automatic grids to use for block processing of array-like objects.
- `ArrayGrid` for the formal representation of grids and viewports.
- `read_block` and `write_block`.
- `MulticoreParam`, `SnowParam`, and `bpparam`, from the `BiocParallel` package.
- `DelayedArray` objects.

**Examples**

```r
m <- matrix(1:60, nrow=10)
m_grid <- defaultAutoGrid(m, block.length=16, block.shape="hypercube")

## blockApply()
blockApply(m, identity, grid=m_grid)
blockApply(m, sum, grid=m_grid)
blockApply(m, function(block) {block + currentBlockId()*1e3}, grid=m_grid)
blockApply(m, function(block) currentViewport(), grid=m_grid)
blockApply(m, dim, grid=m_grid)

## The grid does not need to be regularly spaced:
a <- array(runif(8000), dim=c(25, 40, 8))
a_tickmarks <- list(c(7L, 15L, 25L), c(14L, 22L, 40L), c(2L, 8L))
a_grid <- ArbitraryArrayGrid(a_tickmarks)
a_grid
blockApply(a, function(block) sum(log(block + 0.5)), grid=a_grid)
```
## See block processing in action:
```
blockApply(m, function(block) sum(log(block + 0.5)), grid=m_grid,
           verbose=TRUE)
```

## Use parallel evaluation:
```
library(BiocParallel)
if (.Platform$OS.type != "windows") {
  BPPARAM <- MulticoreParam(workers=4)
} else {
  # MulticoreParam() is not supported on Windows so we use
  # SnowParam() on this platform.
  BPPARAM <- SnowParam(4)
}
blockApply(m, function(block) sum(log(block + 0.5)), grid=m_grid,
           BPPARAM=BPPARAM, verbose=TRUE)
```

## Note that blocks can be visited in any order!

### blockReduce()
```
FUN <- function(block, init) anyNA(block) || init
blockReduce(FUN, m, init=FALSE, grid=m_grid, verbose=TRUE)
```
```
m[10, 1] <- NA
blockReduce(FUN, m, init=FALSE, grid=m_grid, verbose=TRUE)
```

## With early bailout:
```
blockReduce(FUN, m, init=FALSE, BREAKIF=identity, grid=m_grid,
           verbose=TRUE)
```

## Note that this is how the anyNA() method for DelayedArray objects is
## implemented.

---

**ConstantArray**

A *DelayedArray* subclass that contains a constant value

---

### Description

A *DelayedArray* subclass to efficiently mimic an array containing a constant value, without actually creating said array in memory.

### Usage

```
## Constructor function:
ConstantArray(dim, value=NA)
```
DelayedAbind-class

Arguments

- **dim**: The dimensions (specified as an integer vector) of the ConstantArray object to create.
- **value**: Vector (atomic or list) of length 1, containing the value to fill the matrix.

Details

This class allows us to efficiently create arrays containing a single value. For example, we can create matrices full of NA values, to serve as placeholders for missing assays when combining SummarizedExperiment objects.

Value

A ConstantArray (or ConstantMatrix) object. (Note that ConstantMatrix extends ConstantArray.)

Author(s)

Aaron Lun

See Also

- DelayedArray objects.
- DelayedArray-utils for common operations on DelayedArray objects.
- RleArray objects for representing in-memory Run Length Encoded array-like datasets.

Examples

```r
## This would ordinarily take up 8 TB of memory:
CM <- ConstantArray(c(1e6, 1e6), value=NA_real_)
CM

CM2 <- ConstantArray(c(4, 1e6), value=55)
rbind(CM, CM2)
```

Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedAbind class provides a formal representation of a delayed `abind()` operation. It is a concrete subclass of the DelayedNaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:
DelayedAbind objects are used inside a DelayedArray object to represent the delayed `abind()` operations carried by the object. They’re never exposed to the end user and are not intended to be manipulated directly.

Usage

```r
## S4 method for signature 'DelayedAbind'
is_noop(x)
## S4 method for signature 'DelayedAbind'
summary(object, ...)
## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedAbind'
dim(x)
## S4 method for signature 'DelayedAbind'
dimnames(x)
## S4 method for signature 'DelayedAbind'
extract_array(x, index)
## ~ ~ ~ Propagation of sparsity ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedAbind'
is_sparse(x)
## S4 method for signature 'DelayedAbind'
extract_sparse_array(x, index)
```

Arguments

- `x`, `object` A DelayedAbind object.
- `index` See ?extract_array for a description of the index argument.
- `...` Not used.

See Also

- DelayedOp objects.
• **showtree** to visualize the nodes and access the leaves in the tree of delayed operations carried by a **DelayedArray** object.

• **extract_array** and **extract_sparse_array**.

## Examples

```r
## DelayedAbind extends DelayedNaryOp which extends DelayedOp:
extends("DelayedAbind")

## BASIC EXAMPLE
## ---------------------------------------------------------------------
m1 <- matrix(101:128, ncol=4)
m2 <- matrix(runif(16), ncol=4)
M1 <- DelayedArray(m1)
M2 <- DelayedArray(m2)
showtree(M1)
showtree(M2)

M3 <- rbind(M1, M2)
showtree(M3)
class(M3@seed)  # a DelayedAbind object

M4 <- cbind(t(M1), M2)
showtree(M4)
class(M4@seed)  # a DelayedAbind object

## PROPAGATION OF SPARSITY
## ---------------------------------------------------------------------
## DelayedAbind objects always propagate sparsity (given that all the
## input arrays are sparse).

sm1 <- sparseMatrix(i=c(1, 1, 7, 7), j=c(1, 4, 1, 4),
x=c(11, 14, 71, 74), dims=c(7, 4))
SM1 <- DelayedArray(sm1)
sm2 <- sparseMatrix(i=c(1, 1, 4, 4), j=c(1, 4, 1, 4),
x=c(11, 14, 41, 44), dims=c(4, 4))
SM2 <- DelayedArray(sm2)
showtree(SM1)
showtree(SM2)
is_sparse(SM1)  # TRUE
is_sparse(SM2)  # TRUE

SM3 <- rbind(SM1, SM2)
showtree(SM3)
class(SM3@seed)  # a DelayedAbind object
is_sparse(SM3@seed)  # TRUE

SM4 <- cbind(SM2, t(SM1))
showtree(SM4)
class(SM4@seed)  # a DelayedAbind object
```
DelayedAperm-class

Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedAperm class provides a formal representation of a delayed "extended aperm()" operation, that is, of a delayed aperm() that can drop and/or add ineffective dimensions. Note that since only ineffective dimensions (i.e. dimensions with an extent of 1) can be dropped or added, the length of the output array is guaranteed to be the same as the length of the input array.

DelayedAperm is a concrete subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
   ^
  |  
DelayedUnaryOp
   ^
  |  
DelayedAperm
```

DelayedAperm objects are used inside a DelayedArray object to represent the delayed "extended aperm()" operations carried by the object. They're never exposed to the end user and are not intended to be manipulated directly.
## Usage

### S4 method for signature 'DelayedAperm'

```r
is_noop(x)
```

### S4 method for signature 'DelayedAperm'

```r
summary(object, ...)
```

### ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~

stopifnot(class(SA@seed) == "DelayedAperm")
stopifnot(is_sparse(SA@seed))

---

**Description**

Wrapping an array-like object (typically an on-disk object) in a DelayedArray object allows one to perform common array operations on it without loading the object in memory. In order to reduce memory usage and optimize performance, operations on the object are either delayed or executed using a block processing mechanism.
DelayedArray-class

Usage

DelayedArray(seed)  # constructor function
type(x)

Arguments

seed  An array-like object.
x     Typically a DelayedArray object. More generally type() is expected to work on any array-like object (that is, any object for which dim(x) is not NULL), or any ordinary vector (i.e. atomic or non-atomic).

In-memory versus on-disk realization

To realize a DelayedArray object (i.e. to trigger execution of the delayed operations carried by the object and return the result as an ordinary array), call as.array on it. However this realizes the full object at once in memory which could require too much memory if the object is big. A big DelayedArray object is preferably realized on disk e.g. by calling writeHDF5Array on it (this function is defined in the HDF5Array package) or coercing it to an HDF5Array object with as(x,"HDF5Array"). Other on-disk backends can be supported. This uses a block processing strategy so that the full object is not realized at once in memory. Instead the object is processed block by block i.e. the blocks are realized in memory and written to disk one at a time. See ?writeHDF5Array in the HDF5Array package for more information about this.

Accessors

DelayedArray objects support the same set of getters as ordinary arrays i.e. dim(), length(), and dimnames(). In addition, they support type(), nseed(), seed(), and path().

type() is the DelayedArray equivalent of typeof() (or storage.mode()) for ordinary arrays and vectors. Note that, for convenience and consistency, type() also supports ordinary arrays and vectors. It should also support any array-like object, that is, any object \( x \) for which \( \text{dim}(x) \) is not NULL.

dimnames(), seed(), and path() also work as setters.

Subsetting

A DelayedArray object can be subsetted with \([\) like an ordinary array, but with the following differences:

- \textbf{\textit{N-dimensional single bracket subsetting}} (i.e. subsetting of the form \( x[i_1,i_2,\ldots,i_n] \) with one (possibly missing) subscript per dimension) returns a DelayedArray object where the subsetting is actually \textit{delayed}. So it's a very light operation. One notable exception is when drop=TRUE and the result has only one dimension, in which case it is \textit{realized} as an ordinary vector (atomic or list). Note that NAs in the subscripts are not supported.

- \textbf{\textit{1D-style single bracket subsetting}} (i.e. subsetting of the form \( x[i] \)) only works if the subscript \( i \) is a numeric or logical vector, or a logical array-like object with the same dimensions as \( x \), or a numeric matrix with one column per dimension in \( x \). When \( i \) is a numeric vector, all the indices in it must be \( \geq 1 \) and \( \leq \text{length}(x) \). NAs in the subscripts are not supported. This is NOT a delayed operation (block processing is triggered) i.e. the result is \textit{realized} as an
ordinary vector (atomic or list). One exception is when x has only one dimension and drop is set to FALSE, in which case the subsetting is delayed.

Subsetting with [[ is supported but only the 1D-style form of it at the moment, that is, subsetting of the form x[[i]] where i is a single numeric value >= 1 and <= length(x). It is equivalent to x[i][[1]].

Subassignment to a DelayedArray object with [<- is also supported like with an ordinary array, but with the following restrictions:

- **N-dimensional subassignment** (i.e. subassignment of the form x[i_1,i_2,...,i_n] <-value with one (possibly missing) subscript per dimension) only accepts a replacement value (a.k.a. right value) that is an array-like object (e.g. ordinary array, dgCMatrix object, DelayedArray object, etc...) or an ordinary vector (atomic or list) of length 1.

- **1D-style subassignment** (a.k.a. 1D-style subassignment, that is, subassignment of the form x[i] <-value) only works if the subscript i is a logical DelayedArray object of the same dimensions as x and if the replacement value is an ordinary vector (atomic or list) of length 1.

- **Filling with a vector**, that is, subassignment of the form x[] <-v where v is an ordinary vector (atomic or list), is only supported if the length of the vector is a divisor of nrow(x).

These 3 forms of subassignment are implemented as delayed operations so are very light.

Single value replacement (x[[...]] <-value) is not supported yet.

### See Also

- `showtree` for DelayedArray accessors nseed, seed, and path.
- `realize` for realizing a DelayedArray object in memory or on disk.
- `blockApply` and family for convenient block processing of an array-like object.
- DelayedArray-utils for common operations on DelayedArray objects.
- DelayedMatrix-utils for common operations on DelayedMatrix objects.
- DelayedArray-stats for statistical functions on DelayedArray objects.
- DelayedMatrix-stats for DelayedMatrix row/col summarization.
- ConstantArray objects for mimicking an array containing a constant value, without actually creating said array in memory.
- RleArray objects for representing in-memory Run Length Encoded array-like datasets.
- HDF5Array objects in the HDF5Array package.
- DataFrame objects in the S4Vectors package.
- array objects in base R.

### Examples

```r
## A. WRAP AN ORDINARY ARRAY IN A DelayedArray OBJECT
a <- array(runif(1500000), dim=c(10000, 30, 5))
A <- DelayedArray(a)
```

## The seed of a DelayedArray object is **always** treated as a
## "read-only" object so will never be modified by the operations
## we perform on A:
stopifnot(identical(a, seed(A)))
type(A)

## N-dimensional single bracket subsetting:
m <- a[11:20 , 5, -3]  # an ordinary matrix
stopifnot(identical(m, as.array(M)))

## 1D-style single bracket subsetting:
A[A <= 1e-5]
stopifnot(identical(a[a <= 1e-5], A[A <= 1e-5]))

## Subassignment:
A[A < 0.2] <- NA
a[a < 0.2] <- NA
stopifnot(identical(a, as.array(A)))
A[2:5, 1:2, ] <- array(1:40, c(4, 2, 5))
a[2:5, 1:2, ] <- array(1:40, c(4, 2, 5))
stopifnot(identical(a, as.array(A)))

## Other operations:
crazy <- function(x) (5 * x[ , , 1]^3 + 1L) * log(x[ , , 2])
b <- crazy(a)
head(b)
B <- crazy(A)  # very fast! (all operations are delayed)
B
cs <- colSums(b)
CS <- colSums(B)
stopifnot(identical(cs, CS))

## B. WRAP A DataFrame OBJECT IN A DelayedArray OBJECT
## Generate random coverage and score along an imaginary chromosome:
cov <- Rle(sample(20, 5000, replace=TRUE), sample(6, 5000, replace=TRUE))
score <- Rle(sample(100, nrun(cov), replace=TRUE), runLength(cov))
DF <- DataFrame(cov, score)
A2 <- DelayedArray(DF)
A2
seed(A2)  # 'DF'

cf coercion of a DelayedMatrix object to DataFrame produces a DataFrame
## object with Rle columns:
as(A2, "DataFrame")
stopifnot(identical(DF, as(A2, "DataFrame")))
t(A2) # transposition is delayed so is very fast and memory-efficient
colSums(A2)

### C. AN HDF5Array OBJECT IS A (PARTICULAR KIND OF) DelayedArray OBJECT
### ---------------------------------------------------------------------
library(HDF5Array)
A3 <- as(a, "HDF5Array") # write 'a' to an HDF5 file
A3
is(A3, "DelayedArray") # TRUE
seed(A3) # an HDF5ArraySeed object
B3 <- crazy(A3) # very fast! (all operations are delayed)
B3 # not an HDF5Array object anymore because
# now it carries delayed operations
CS3 <- colSums(B3)
stopifnot(identical(cs, CS3))

### D. PERFORM THE DELAYED OPERATIONS
### ---------------------------------------------------------------------
as(B3, "HDF5Array") # "realize" 'B3' on disk

### If this is just an intermediate result, you can either keep going
### with B3 or replace it with its "realized" version:
B3 <- as(B3, "HDF5Array") # no more delayed operations on new 'B3'
seed(B3)
path(B3)

### For convenience, realize() can be used instead of explicit coercion.
### The current "automatic realization backend" controls where
### realization happens e.g. in memory if set to NULL or in an HDF5
### file if set to "HDF5Array":
D <- cbind(B3, exp(B3))
D
setAutoRealizationBackend("HDF5Array")
D <- realize(D)
D
### See '?setAutoRealizationBackend' for more information about
### "realization backends".

### E. MODIFY THE PATH OF A DelayedArray OBJECT
### ---------------------------------------------------------------------
### This can be useful if the file containing the array data is on a
### shared partition but the exact path to the partition depends on the
### machine from which the data is being accessed.
### For example:

### Not run:
library(HDF5Array)
A <- HDF5Array("/path/to/lab_data/my_precious_data.h5")
path(A)

## Operate on A...
## Now A carries delayed operations.
## Make sure path(A) still works:
path(A)

## Save A:
save(A, file="A.rda")

## A.rda should be small (it doesn’t contain the array data).
## Send it to a co-worker that has access to my_precious_data.h5.

## Co-worker loads it:
load("A.rda")
path(A)

## A is broken because path(A) is incorrect for co-worker:
A # error!

## Co-worker fixes the path (in this case this is better done using the 
## dirname() setter rather than the path() setter):
dirname(A) <- "E:/other/path/to/lab_data"

## A "works" again:
A

## End(Not run)

## F. WRAP A SPARSE MATRIX IN A DelayedArray OBJECT
##------------------------------------------------------------
## Not run:
M <- 75000L
N <- 1800L
p <- sparseMatrix(sample(M, 9000000, replace=TRUE),
  sample(N, 9000000, replace=TRUE),
  x=runif(9000000), dims=c(M, N))
P <- DelayedArray(p)
P

p2 <- as(P, "sparseMatrix")
stopifnot(identical(p, p2))

## The following is based on the following post by Murat Tasan on the 
## R-help mailing list:
## https://stat.ethz.ch/pipermail/r-help/2017-May/446702.html

## As pointed out by Murat, the straight-forward row normalization
## directly on sparse matrix ’p’ would consume too much memory:
row_normalized_p <- p / rowSums(p[,2]) # consumes too much memory
## because the rowSums() result is being recycled (appropriately) into a
## *dense* matrix with dimensions equal to dim(p).
## Murat came up with the following solution that is very fast and memory-efficient:

```r
row_normalized_p1 <- Diagonal(x=1/sqrt(Matrix::rowSums(p^2)))
```

## With a DelayedArray object, the straight-forward approach uses a block processing strategy behind the scene so it doesn't consume too much memory.

## First, let's see block processing in action:

```r
DelayedArray:::set_verbose_block_processing(TRUE)
```

## and check the automatic block size:

```r
getAutoBlockSize()
```

```r
row_normalized_P <- P / sqrt(DelayedArray::rowSums(P^2))
```

## Increasing the block size increases the speed but also memory usage:

```r
setAutoBlockSize(2e8)
row_normalized_P2 <- P / sqrt(DelayedArray::rowSums(P^2))
```

```r
stopifnot(all.equal(row_normalized_P, row_normalized_P2))
```

## Back to sparse representation:

```r
DelayedArray:::set_verbose_block_processing(FALSE)
row_normalized_p2 <- as(row_normalized_P, "sparseMatrix")
```

```r
stopifnot(all.equal(row_normalized_p1, row_normalized_p2))
```

```r
setAutoBlockSize() # reset automatic block size to factory settings
```

## End(Not run)

### DelayedArray-stats

#### Statistical functions on DelayedArray objects

**Description**

Statistical functions on DelayedArray objects.

All these functions are implemented as delayed operations.

**Usage**

```r
## --- The Normal Distribution ------ ##

## S4 method for signature 'DelayedArray'
dnorm(x, mean=0, sd=1, log=FALSE)
## S4 method for signature 'DelayedArray'
pnorm(q, mean=0, sd=1, lower.tail=TRUE, log.p=FALSE)
## S4 method for signature 'DelayedArray'
qnorm(p, mean=0, sd=1, lower.tail=TRUE, log.p=FALSE)

## --- The Binomial Distribution --- ##
```
## S4 method for signature 'DelayedArray'
dbinom(x, size, prob, log=FALSE)
## S4 method for signature 'DelayedArray'
pbinom(q, size, prob, lower.tail=TRUE, log.p=FALSE)
## S4 method for signature 'DelayedArray'
qbinom(p, size, prob, lower.tail=TRUE, log.p=FALSE)

## --- The Poisson Distribution ---- ##

## S4 method for signature 'DelayedArray'
dpois(x, lambda, log=FALSE)
## S4 method for signature 'DelayedArray'
p pois(q, lambda, lower.tail=TRUE, log.p=FALSE)
## S4 method for signature 'DelayedArray'
qpois(p, lambda, lower.tail=TRUE, log.p=FALSE)

## --- The Logistic Distribution --- ##

## S4 method for signature 'DelayedArray'
dlogis(x, location=0, scale=1, log=FALSE)
## S4 method for signature 'DelayedArray'
plogis(q, location=0, scale=1, lower.tail=TRUE, log.p=FALSE)
## S4 method for signature 'DelayedArray'
qlogis(p, location=0, scale=1, lower.tail=TRUE, log.p=FALSE)

Arguments

x, q, p
A DelayedArray object.
mean, sd, log, lower.tail, log.p, size, prob, lambda, location, scale
See ?stats::dnorm, ?stats::dbinom, ?stats::dpois, and ?stats::dlogis,
for a description of these arguments.

See Also

- dnorm, dbinom, dpois, and dlogis in the stats package for the corresponding operations on
ordinary arrays or matrices.
- DelayedMatrix-stats for DelayedMatrix row/col summarization.
- DelayedArray objects.
- HDF5Array objects in the HDF5Array package.
- array objects in base R.

Examples

a <- array(4 * runif(1500000), dim=c(10000, 30, 5))
A <- DelayedArray(a)
A
A2 <- dnorm(A + 1)[ , , -3]  # very fast! (operations are delayed)
A2

a2 <- as.array(A2)  # "realize" 'A2' in memory (as an ordinary array)
DelayedArray(a2) == A2  # DelayedArray object of type "logical"
stopifnot(all(DelayedArray(a2) == A2))

library(HDF5Array)
A3 <- as(A2, "HDF5Array")  # "realize" 'A2' on disk (as an HDF5Array object)
A3 == A2  # DelayedArray object of type "logical"
stopifnot(all(A3 == A2))

## See '?DelayedArray' for general information about DelayedArray objects
## and their "realization".

---

### Description

Common operations on DelayedArray objects.

### Details

The operations currently supported on DelayedArray objects are:

Delayed operations:

- rbind and cbind
- all the members of the Ops, Math, and Math2 groups
- !
- is.na, is.finite, is.infinite, is.nan
- type<-  
- lengths
- nchar, tolower, toupper, grepl, sub, gsub
- pmax2 and pmin2
- sweep
- scale (when the supplied center and scale are not TRUE)
- statistical functions like dnorm, dbinom, dpois, and dlogis (for the Normal, Binomial, Poisson, and Logistic distribution, respectively) and related functions (documented in DelayedArray-stats)
Block-processed operations:

- `anyNA`, `which`
- `unique`, `table`
- all the members of the `Summary` group
- `mean`
- `apply`

Mix delayed and block-processed operations:

- `scale` (when the supplied `center` and/or `scale` are TRUE)

See Also

- `cbind` in the `base` package for `rbind/chind`'ing ordinary arrays.
- `arbind` and `acbind` in this package (`DelayedArray`) for binding ordinary arrays of arbitrary dimensions along their rows or columns.
- `is.na`, `.table`, `mean`, `apply`, and `%*%` in the `base` package for the corresponding operations on ordinary arrays or matrices.
- `DelayedMatrix-utils` for common operations on `DelayedMatrix` objects.
- `DelayedArray-stats` for statistical functions on `DelayedArray` objects.
- `DelayedMatrix-stats` for `DelayedMatrix` row/col summarization.
- `DelayedArray` objects.
- `HDF5Array` objects in the `HDF5Array` package.
- `S4groupGeneric` in the `methods` package for the members of the `Ops`, `Math`, and `Math2` groups.
- `sweep` and `scale` in the `base` package.

Examples

```r
## ____________________________________________________________
## BIND DelayedArray OBJECTS
## ____________________________________________________________
## DelayedArray objects can be bound along their 1st (rows) or 2nd
## (columns) dimension with `rbind()` or `cbind()`. These operations are
## equivalent to `arbind()` and `acbind()`, respectively, and are all
## delayed.
##
## # On 2D objects:
library(HDF5Array)
toy_h5 <- system.file("extdata", "toy.h5", package="HDF5Array")
h5ls(toy_h5)

M1 <- HDF5Array(toy_h5, "M1")
M2 <- HDF5Array(toy_h5, "M2")

M12 <- rbind(M1, t(M2))  # delayed
```

```
DelayedArray-utils

M12
colMeans(M12)  # block-processed

## On objects with more than 2 dimensions:
example(arbind)  # to create arrays a1, a2, a3

A1 <- DelayedArray(a1)
A2 <- DelayedArray(a2)
A3 <- DelayedArray(a3)
A123 <- rbind(A1, A2, A3)  # delayed
A123

## On 1D objects:
v1 <- array(11:15, 5, dimnames=list(LETTERS[1:5]))
v2 <- array(letters[1:3])
V1 <- DelayedArray(v1)
V2 <- DelayedArray(v2)
V12 <- rbind(V1, V2)
V12

## Not run: cbind(V1, V2)  # Error! (the objects to cbind() must have at least 2 
# dimensions)

## End(Not run)

## Note that base::rbind() and base::cbind() do something completely 
## different on ordinary arrays that are not matrices. They treat them 
## as if they were vectors:
rbind(a1, a2, a3)
cbind(a1, a2, a3)
rbind(v1, v2)

## Also note that DelayedArray objects of arbitrary dimensions can be 
## stored inside a DataFrame object as long as they all have the same 
## first dimension (nrow()):
DF <- DataFrame(M=I(tail(M1, n=5)), A=I(A3), V=I(V1))
DF[-3, ]
DF2 <- rbind(DF, DF)
DF2$V

## Sanity checks:
m1 <- as.matrix(M1)
m2 <- as.matrix(M2)
stopifnot(identical(rbind(m1, t(m2)), as.matrix(M12)))
stopifnot(identical(arbind(a1, a2, a3), as.array(A123)))
stopifnot(identical(arbind(v1, v2), as.array(V12)))

## MORE OPERATIONS
DelayedMatrix-stats

## Description

Only a small number of row/col summarization methods are provided by the DelayedArray package.

See the DelayedMatrixStats package for an extensive set of row/col summarization methods.

## Usage

```r
## S4 method for signature 'DelayedMatrix'
rowSums(x, na.rm=FALSE, dims=1)
## S4 method for signature 'DelayedMatrix'
colSums(x, na.rm=FALSE, dims=1)
## S4 method for signature 'DelayedMatrix'
rowMeans(x, na.rm=FALSE, dims=1)
## S4 method for signature 'DelayedMatrix'
colMeans(x, na.rm=FALSE, dims=1)
```
### S4 method for signature 'DelayedMatrix'
rowMins(x, rows=NULL, cols=NULL, na.rm=FALSE)

### S4 method for signature 'DelayedMatrix'
colMins(x, rows=NULL, cols=NULL, na.rm=FALSE)

### S4 method for signature 'DelayedMatrix'
rowMaxs(x, rows=NULL, cols=NULL, na.rm=FALSE)

### S4 method for signature 'DelayedMatrix'
colMaxs(x, rows=NULL, cols=NULL, na.rm=FALSE)

### S4 method for signature 'DelayedMatrix'
rowRanges(x, rows=NULL, cols=NULL, na.rm=FALSE)

### S4 method for signature 'DelayedMatrix'
colRanges(x, rows=NULL, cols=NULL, na.rm=FALSE)

#### Arguments

- **x**
  - A `DelayedMatrix` object.

- **na.rm**
  - Should missing values (including `NaN`) be omitted from the calculations?

- **dims, rows, cols**
  - These arguments are not supported. Don’t use them.

#### Details

All these operations are block-processed.

#### See Also

- The `DelayedMatrixStats` package for more row/col summarization methods for `DelayedMatrix` objects.
- `rowSums` in the `base` package and `rowMaxs` in the `matrixStats` package for row/col summarization of an ordinary matrix.
- `DelayedMatrix-utils` for other common operations on `DelayedMatrix` objects.
- `DelayedMatrix` objects.
- `matrix` objects in base R.

#### Examples

```r
library(HDF5Array)
toy_h5 <- system.file("extdata", "toy.h5", package="HDF5Array")
h5ls(toy_h5)

M1 <- HDF5Array(toy_h5, "M1")
M2 <- HDF5Array(toy_h5, "M2")

M12 <- rbind(M1, t(M2)) # delayed
```
## All these operations are block-processed.

rowSums(M12)
colSums(M12)

rowMeans(M12)
colMeans(M12)

rmins <- rowMins(M12)
cmins <- colMins(M12)

rmaxs <- rowMaxs(M12)
cmaxs <- colMaxs(M12)

rranges <- rowRanges(M12)
cranges <- colRanges(M12)

## Sanity checks:

m12 <- rbind(as.matrix(M1), t(as.matrix(M2)))
stopifnot(identical(rowSums(M12), rowSums(m12)))
stopifnot(identical(colSums(M12), colSums(m12)))
stopifnot(identical(rowMeans(M12), rowMeans(m12)))
stopifnot(identical(colMeans(M12), colMeans(m12)))
stopifnot(identical(rmins, rowMins(m12)))
stopifnot(identical(cmins, colMins(m12)))
stopifnot(identical(rmaxs, rowMaxs(m12)))
stopifnot(identical(cmaxs, colMaxs(m12)))
stopifnot(identical(rranges, cbind(rmins, rmaxs, deparse.level=0)))
stopifnot(identical(cranges, cbind(cmins, cmaxs, deparse.level=0)))

---

### Description

Common operations on DelayedMatrix objects.

### Details

In addition to the operations supported on DelayedArray objects, DelayedMatrix objects support the following operations:

- Delayed operations:
  - `t`

- Block-processed operations:
  - `rowsum` and `colsum`
  - matrix multiplication `(%*%)` of an ordinary matrix by a DelayedMatrix object
  - matrix row/col summarization (see `?DelayedMatrix-stats`)

---

**DelayedMatrix-utils**

*Common operations on DelayedMatrix objects*
See Also

- `rowsum` in the `base` package for computing column sums across rows of an ordinary matrix for each level of a grouping variable.
- `DelayedArray-utils` for common operations on `DelayedArray` objects.
- `DelayedArray-stats` for statistical functions on `DelayedArray` objects.
- `DelayedMatrix-stats` for `DelayedMatrix` row/col summarization.
- `setAutoRealizationBackend` for how to set an automatic realization backend.
- `writeHDF5Array` in the `HDF5Array` package for writing an array-like object to an HDF5 file and other low-level utilities to control the location of automatically created HDF5 datasets.
- `DelayedArray` objects.
- `HDF5Array` objects in the `HDF5Array` package.
- `array` objects in base R.

Examples

```r
## ---------------------------------------------------------------------
## rowsum() / colsum()
## ---------------------------------------------------------------------
library(HDF5Array)
set.seed(123)
m0 <- matrix(runif(14400000), ncol=2250,
dimnames=list(NULL, sprintf("C%04d", 1:2250)))
M0 <- writeHDF5Array(m0, chunkdim=c(200, 250))
dimnames(M0) <- dimnames(m0)

## --- rowsum() ---
group <- sample(90, nrow(M0), replace=TRUE) # define groups of rows
rs <- rowsum(M0, group)
rs[1:5, 1:8]
rs2 <- rowsum(M0, group, reorder=FALSE)
rs2[1:5, 1:8]

## Let's see block processing in action:
DelayedArray:::set_verbose_block_processing(TRUE)
setAutoBlockSize(2e6)
rs3 <- rowsum(M0, group)
setAutoBlockSize()
DelayedArray:::set_verbose_block_processing(FALSE)

## Sanity checks:
stopifnot(all.equal(rowsum(m0, group), rs))
stopifnot(all.equal(rowsum(m0, group, reorder=FALSE), rs2))
stopifnot(all.equal(rs, rs3))

## --- colsum() ---
group <- sample(30, ncol(M0), replace=TRUE) # define groups of cols
cs <- colsum(M0, group)
```

cs[1:5, 1:7]
cs2 <- colsum(M0, group, reorder=FALSE)
cs2[1:5, 1:7]

## Sanity checks:
stopifnot(all.equal(colsum(m0, group), cs))
stopifnot(all.equal(cs, t(rowsum(t(m0), group))))
stopifnot(all.equal(cs, t(rowsum(t(M0), group))))
stopifnot(all.equal(colsum(m0, group, reorder=FALSE), cs2))
stopifnot(all.equal(cs2, t(rowsum(t(m0), group, reorder=FALSE))))
stopifnot(all.equal(cs2, t(rowsum(t(M0), group, reorder=FALSE))))

## MATRIX MULTIPLICATION
library(HDF5Array)
toy_h5 <- system.file("extdata", "toy.h5", package="HDF5Array")
h5ls(toy_h5)
M1 <- HDF5Array(toy_h5)

## Matrix multiplication is not delayed: the output matrix is realized
## block by block. The current "automatic realization backend" controls
## where realization happens e.g. in memory as an ordinary matrix if not
## (i.e. set to NULL) or in an HDF5 file if set to "HDF5Array".
## See
## ?setAutoRealizationBackend for more information about
## "realization backends".
## The output matrix is returned as a DelayedMatrix object with no delayed
## operations on it. The exact class of the object depends on the backend
## e.g. it will be HDF5Matrix with "HDF5Array" backend.

m <- matrix(runif(50000), ncol=nrow(M1))

## Set backend to NULL for in-memory realization:
setAutoRealizationBackend()
P1 <- m %*% M1
P1

## Set backend to HDF5Array for realization in HDF5 file:
setAutoRealizationBackend("HDF5Array")

## With the HDF5Array backend, the output matrix will be written to an
## automatic location on disk:
getHDF5DumpFile() # HDF5 file where the output matrix will be written
lsHDF5DumpFile()
P2 <- m %*% M1
P2

lsHDF5DumpFile()

## Use setHDF5DumpFile() and setHDF5DumpName() from the HDF5Array package
## to control the location of automatically created HDF5 datasets.
DelayedNaryIsoOp-class

```r
stopifnot(identical(dim(P1), dim(P2)),
  all.equal(as.array(P1), as.array(P2)))
```

## DelayedNaryIsoOp-class

### DelayedNaryIsoOp objects

#### Description

NOTE: This man page is about `DelayedArray` internals and is provided for developers and advanced users only.

The `DelayedNaryIsoOp` class provides a formal representation of a *delayed N-ary isometric operation*. It is a concrete subclass of the `DelayedNaryOp` virtual class, which itself is a subclass of the `DelayedOp` virtual class:

```
  DelayedOp
  ^
  |   DelayedNaryOp
  ^
  |   DelayedNaryIsoOp
```

`DelayedNaryIsoOp` objects are used inside a `DelayedArray` object to represent the *delayed N-ary isometric operation* carried by the object. They’re never exposed to the end user and are not intended to be manipulated directly.

#### Usage

```r
## S4 method for signature 'DelayedNaryIsoOp'
summary(object, ...)
```

```r
## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedNaryIsoOp'
dim(x)
```

```r
## S4 method for signature 'DelayedNaryIsoOp'
dimnames(x)
```

```r
## S4 method for signature 'DelayedNaryIsoOp'
extract_array(x, index)
```

```r
## ~ ~ ~ Propagation of sparsity ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedNaryIsoOp'
```
### DelayedNaryIsoOp-class

is_sparse(x)

```r
## S4 method for signature 'DelayedNaryIsoOp'
extract_sparse_array(x, index)
```

**Arguments**

- **x**, object: A DelayedNaryIsoOp object.
- **index**: See `?extract_array` for a description of the `index` argument.
- **...**: Not used.

**See Also**

- `DelayedOp` objects.
- `showtree` to visualize the nodes and access the leaves in the tree of delayed operations carried by a `DelayedArray` object.
- `extract_array` and `extract_sparse_array`.

### Examples

```r
## DelayedNaryIsoOp extends DelayedNaryOp which extends DelayedOp:
extends("DelayedNaryIsoOp")
```

```r
## BASIC EXAMPLE
m1 <- matrix(101:130, ncol=5)
m2 <- matrix(runif(30), ncol=5)
M1 <- DelayedArray(m1)
M2 <- DelayedArray(m2)
showtree(M1)
showtree(M2)
M <- M1 / M2
showtree(M)
class(M@seed) # a DelayedNaryIsoOp object
```

```r
## PROPOSITION OF SPARSITY
sm1 <- sparseMatrix(i=c(1, 6), j=c(1, 4), x=c(11, 64), dims=6:5)
SM1 <- DelayedArray(sm1)
sm2 <- sparseMatrix(i=c(2, 6), j=c(1, 5), x=c(21, 65), dims=6:5)
SM2 <- DelayedArray(sm2)
showtree(SM1)
showtree(SM2)
is_sparse(SM1) # TRUE
is_sparse(SM2) # TRUE
SM3 <- SM1 - SM2
showtree(SM3)
```
DelayedOp-class 45

class(SM3@seed)  # a DelayedNaryIsoOp object
is_sparse(SM3@seed)  # TRUE

M4 <- SM1 / SM2
showtree(M4)
class(M4@seed)  # a DelayedNaryIsoOp object
is_sparse(M4@seed)  # FALSE

## SANITY CHECKS
stopifnot(class(M@seed) == "DelayedNaryIsoOp")
stopifnot(class(SM3@seed) == "DelayedNaryIsoOp")
stopifnot(is_sparse(SM3@seed))
stopifnot(class(M4@seed) == "DelayedNaryIsoOp")
stopifnot(!is_sparse(M4@seed))

----------

DelayedOp-class  

DelayedOp objects

Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

In a DelayedArray object, the delayed operations are stored as a tree where the leaves are operands and the nodes are the operations. Each node in the tree is a DelayedOp derivative representing a particular delayed operation.

DelayedOp is a virtual class with 8 concrete subclasses. Each subclass provides a formal representation for a particular kind of delayed operation.

Usage

is_noop(x)

Arguments

x  A DelayedSubset, DelayedAperm, or DelayedSetDimnames object.

Details

8 types of nodes are currently supported. Each type is a DelayedOp subclass:

<table>
<thead>
<tr>
<th>Node type</th>
<th>Represented operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>DelayedOp (VIRTUAL)</td>
<td>Multi-dimensional single bracket</td>
</tr>
</tbody>
</table>

* DelayedUnaryOp (VIRTUAL)
  o DelayedSubset

Node type                                | Represented operation                                           |
-----------------------------------------|----------------------------------------------------------------|
DelayedOp (VIRTUAL)                      | Multi-dimensional single bracket                                |
* DelayedUnaryOp (VIRTUAL)                | Multi-dimensional single bracket                                |
  o DelayedSubset                         | Multi-dimensional single bracket                                |
DelayedOp-class

- DelayedAperm Extended aperm() (can drop and/or add ineffective dimensions).
- DelayedUnaryIsoOp (VIRTUAL) Unary op that preserves the geometry.
  - DelayedUnaryIsoOpStack Simple ops stacked together.
  - DelayedUnaryIsoOpWithArgs One op with vector-like arguments along the dimensions of the input.
- DelayedSubassign Multi-dimensional single bracket subassignment.
- DelayedSetDimnames Set/replace the dimnames.

* DelayedNaryOp (VIRTUAL)
  - DelayedNaryIsoOp N-ary op that preserves the geometry.
  - DelayedAbind abind()

All the nodes are array-like objects that must comply with the seed contract i.e. they must support dim(), dimnames(), and extract_array(). See ?extract_array for more information about the seed contract.

is_noop() can only be called on a DelayedSubset, DelayedAperm, or DelayedSetDimnames object at the moment, and will return TRUE if the object represents a no-op.

Note

The DelayedOp virtual class and its 8 concrete subclasses are used inside a DelayedArray object to represent delayed operations carried by the object. They’re never exposed to the end user and are not intended to be manipulated directly.

See Also

- DelayedOp concrete subclasses: DelayedSubset, DelayedAperm, DelayedUnaryIsoOpStack, DelayedUnaryIsoOpWithArgs, DelayedSubassign, DelayedSetDimnames, DelayedNaryIsoOp, and DelayedAbind.
- DelayedArray objects.
- showtree to visualize the nodes and access the leaves in the tree of delayed operations carried by a DelayedArray object.
- simplify to simplify the tree of delayed operations carried by a DelayedArray object.
- extract_array.
DelayedSetDimnames-class

DelayedSetDimnames objects

Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedSetDimnames class provides a formal representation of a delayed "set dimnames" operation. It is a concrete subclass of the DelayedUnaryIsoOp virtual class, which itself is a subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
  ^
  |
DelayedUnaryOp
  ^
  |
DelayedUnaryIsoOp
  ^
  |
DelayedSetDimnames
```

DelayedSetDimnames objects are used inside a DelayedArray object to represent the delayed "set dimnames" operations carried by the object. They're never exposed to the end user and are not intended to be manipulated directly.

Usage

```
## S4 method for signature 'DelayedSetDimnames'
is_noop(x)

## S4 method for signature 'DelayedSetDimnames'
summary(object, ...)

## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## DelayedSetDimnames objects inherit the default dim()
## and extract_array() methods defined for DelayedUnaryIsoOp
## derivatives, but overwrite their dimnames() method.

## S4 method for signature 'DelayedSetDimnames'
dimnames(x)

## ~ ~ ~ Propagation of sparsity ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
```
DelayedSetDimnames-class

DelayedSetDimnames objects inherit the default is_sparse() and extract_sparse_array() methods defined for DelayedUnaryIsoOp derivatives.

Arguments

x, object A DelayedSetDimnames object.

... Not used.

See Also

- DelayedOp objects.
- showtree to visualize the nodes and access the leaves in the tree of delayed operations carried by a DelayedArray object.

Examples

## DelayedSetDimnames extends DelayedUnaryIsoOp, which extends
## DelayedUnaryOp, which extends DelayedOp:
## ---------------------------------------------------------------------
expects("DelayedSetDimnames")
## BASIC EXAMPLE
## ---------------------------------------------------------------------
m0 <- matrix(1:30, ncol=5, dimnames=list(letters[1:6], NULL))
M2 <- M1 <- M0 <- DelayedArray(m0)
showtree(M0)

dimnames(M1) <- list(NULL, LETTERS[1:5])
showtree(M1)
class(M1@seed) # a DelayedSetDimnames object

colnames(M2) <- LETTERS[1:5]
showtree(M2)
class(M2@seed) # a DelayedSetDimnames object

## PROPAGATION OF SPARSITY
## ---------------------------------------------------------------------
## DelayedSetDimnames objects always propagate sparsity.
sm0 <- sparseMatrix(i=c(1, 4), j=c(1, 3), x=c(11, 43), dims=4:3)
SM <- SM0 <- DelayedArray(sm0)
showtree(SM)
is_sparse(SM0) # TRUE

dimnames(SM) <- list(letters[1:4], LETTERS[1:3])
showtree(SM)
class(SM@seed) # a DelayedSetDimnames object
is_sparse(SM@seed) # TRUE
### SANITY CHECKS

```
stopifnot(class(M1@seed) == "DelayedSetDimnames")
stopifnot(class(M2@seed) == "DelayedSetDimnames")
stopifnot(class(SM@seed) == "DelayedSetDimnames")
stopifnot(is_sparse(SM@seed))
```

**Description**

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedSubassign class provides a formal representation of a delayed multi-dimensional single bracket subassignment. It is a concrete subclass of the DelayedUnaryIsoOp virtual class, which itself is a subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
|   
DelayedUnaryOp
|   
DelayedUnaryIsoOp
|   
DelayedSubassign
```

DelayedSubassign objects are used inside a DelayedArray object to represent the delayed multi-dimensional single bracket subassignments carried by the object. They're never exposed to the end user and are not intended to be manipulated directly.

### Usage

```
## S4 method for signature 'DelayedSubassign'
is_noop(x)

## S4 method for signature 'DelayedSubassign'
summary(object, ...)

## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
```
## DelayedSubassign-class

DelayedSubassign objects inherit the default `dim()` and `dimnames()` methods defined for DelayedUnaryIsoOp derivatives, but overwrite their `extract_array()` method.

## S4 method for signature 'DelayedSubassign'

```r
evaluate_array(x, index)
```

## Propagation of sparsity

## S4 method for signature 'DelayedSubassign'

```r
is_sparse(x)
```

## S4 method for signature 'DelayedSubassign'

```r
extract_sparse_array(x, index)
```

### Arguments

- `x`, `object` A DelayedSubassign object.
- `index` See `?extract_array` for a description of the index argument.
- `...` Not used.

### See Also

- `DelayedOp` objects.
- `showtree` to visualize the nodes and access the leaves in the tree of delayed operations carried by a `DelayedArray` object.
- `extract_array` and `extract_sparse_array`.

### Examples

## DelayedSubassign extends DelayedUnaryIsoOp, which extends DelayedUnaryOp, which extends DelayedOp:

```r
extends("DelayedSubassign")
```

## BASIC EXAMPLE

```r
m0 <- matrix(1:30, ncol=5)
M2 <- M1 <- M0 <- DelayedArray(m0)
showtree(M0)
showtree(M1)
class(M1@seed) # a DelayedSubassign object
```

```r
showtree(M2)
class(M2@seed) # a DelayedSubassign object
```
## PROPAGATION OF SPARSITY
## ---------------------------------------------------------------------

## DelayedSubassign objects don't propagate sparsity at the moment, that is, is_sparse() always returns FALSE on them.
## ---------------------------------------------------------------------

## SANITY CHECKS
## ---------------------------------------------------------------------

\[
\text{stopifnot(class(M1@seed) == "DelayedSubassign")}
\]
\[
\text{stopifnot(class(M2@seed) == "DelayedSubassign")}
\]

### Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedSubset class provides a formal representation of a delayed multi-dimensional single bracket subsetting operation. It is a concrete subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
  ^
  |    
DelayedUnaryOp
  ^
  | 
DelayedSubset
```

DelayedSubset objects are used inside a DelayedArray object to represent the delayed multi-dimensional single bracket subsetting operations carried by the object. They're never exposed to the end user and are not intended to be manipulated directly.

### Usage

\[
\text{## S4 method for signature 'DelayedSubset'}
\]
\[
is_noop(x)
\]

\[
\text{## S4 method for signature 'DelayedSubset'}
\]
\[

### DelayedUnaryIsoOpStack-class

DelayedUnaryIsoOpStack objects

Description

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.

The DelayedUnaryIsoOpStack class provides a formal representation of a stack of delayed unary isometric operations, that is, of a group of delayed unary isometric operations stacked (a.k.a. piped) together. It is a concrete subclass of the DelayedUnaryIsoOp virtual class, which itself is a subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
  ^
  |
DelayedUnaryOp
  ^
  |
DelayedUnaryIsoOp
  ^
  |
DelayedUnaryIsoOpStack
```
DelayedUnaryIsoOpStack objects are used inside a DelayedArray object to represent groups of delayed unary isometric operations carried by the object. They’re never exposed to the end user and are not intended to be manipulated directly.

Usage

```r
## S4 method for signature 'DelayedUnaryIsoOpStack'
summary(object, ...)
```

```r
## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## DelayedUnaryIsoOpStack objects inherit the default dim()
## and dimnames() methods defined for DelayedUnaryIsoOp
## derivatives, but overrite their extract_array() method.
##
## S4 method for signature 'DelayedUnaryIsoOpStack'
extract_array(x, index)
```

```r
## ~ ~ ~ Propagation of sparsity ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedUnaryIsoOpStack'
is_sparse(x)
```

```r
## S4 method for signature 'DelayedUnaryIsoOpStack'
extract_sparse_array(x, index)
```

Arguments

- `x, object` A `DelayedUnaryIsoOpStack` object.
- `index` See ?`extract_array` for a description of the `index` argument.
- `...` Not used.

Details

A `DelayedUnaryIsoOpStack` object is used to represent the delayed version of an operation of the form:

```r
out <- a |> OP1 |> OP2 |> ... |> OPk
```

where:

- `OP1, OP2, ..., OPk` are isometric array transformations i.e. operations that return an array with the same dimensions as the input array.
- `a` is the input array.
- The output (`out`) is an array of same dimensions as `a`.

In addition, each operation (`OP`) in the pipe must satisfy the property that each value in the output array must be determined **solely** by the corresponding value in the input array. In other words:
DelayedUnaryIsoOpStack-class

\[ a \mid> \text{OP} \mid> \text{\`[}(i_1, i_2, \ldots, i_n) \quad \text{# i.e. } \text{OP}(a)[i_1, i_2, \ldots, i_n] \]

must be equal to:

\[ a \mid> \text{\`[}(i_1, i_2, \ldots, i_n) \mid> \text{OP} \quad \text{# i.e. } \text{OP}(a[i_1, i_2, \ldots, i_n]) \]

for any valid multidimensional index \((i_1, i_2, \ldots, i_n)\).

We refer to this property as the *locality principle*.

Concrete examples:

1. Things like `is.na()`, `is.finite()`, logical negation `!`, `nchar()`, `tolower()`.
2. Most functions in the *Math* and *Math2* groups e.g. `log()`, `sqrt()`, `abs()`, `ceiling()`, `round()`, etc... Notable exceptions are the `cum*()` functions (`cummin()`, `cummax()`, `cumsum()`, and `cumprod()`): they don’t satisfy the *locality principle*.
3. Operations in the *Ops* group when one operand is an array and the other a scalar e.g. \(a + 10\), \(2^a\), \(a <= 0.5\), etc...

See Also

- *DelayedOp* objects.
- `showtree` to visualize the nodes and access the leaves in the tree of delayed operations carried by a *DelayedArray* object.
- `extract_array` and `extract_sparse_array`.

Examples

```r
## DelayedUnaryIsoOpStack extends DelayedUnaryIsoOp, which extends
## DelayedUnaryOp, which extends DelayedOp:
##  extends("DelayedUnaryIsoOpStack")

## BASIC EXAMPLE
m0 <- matrix(runif(12), ncol=3)
M0 <- DelayedArray(m0)
showtree(M0)
M <- log(1 + M0) / 10
showtree(M)
class(M@seed) # a DelayedUnaryIsoOpStack object

## PROPAGATION OF SPARSITY
sm0 <- sparseMatrix(i=c(1, 4), j=c(1, 3), x=c(11, 43), dims=4:3)
SM0 <- DelayedArray(sm0)
showtree(SM0)
```

DelayedUnaryIsoOpStack-class
is_sparse(SM0)  # TRUE

stopifnot(class(SM4@seed) == "DelayedUnaryIsoOpStack")
stopifnot(is_sparse(SM4@seed))
stopifnot(class(M5@seed) == "DelayedUnaryIsoOpStack")
stopifnot(is_sparse(SM5@seed))

**Description**

NOTE: This man page is about DelayedArray internals and is provided for developers and advanced users only.
The DelayedUnaryIsoOpWithArgs class provides a formal representation of a delayed unary isometric operation with vector-like arguments going along the dimensions of the input array. It is a concrete subclass of the DelayedUnaryIsoOp virtual class, which itself is a subclass of the DelayedUnaryOp virtual class, which itself is a subclass of the DelayedOp virtual class:

```
DelayedOp
  ^
  |  
DelayedUnaryOp
  ^
  |  
DelayedUnaryIsoOp
  ^
  |  
DelayedUnaryIsoOpWithArgs
```

DelayedUnaryIsoOpWithArgs objects are used inside a DelayedArray object to represent the delayed unary isometric operations with vector-like arguments going along the dimensions of the input array carried by the object. They’re never exposed to the end user and are not intended to be manipulated directly.

Usage

```
## S4 method for signature 'DelayedUnaryIsoOpWithArgs'
summary(object, ...)

## ~ ~ ~ Seed contract ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## DelayedUnaryIsoOpWithArgs objects inherit the default dim()
## and dimnames() methods defined for DelayedUnaryIsoOp
## derivatives, but overwrite their extract_array() method.

## S4 method for signature 'DelayedUnaryIsoOpWithArgs'
exttract_array(x, index)

## ~ ~ ~ Propagation of sparsity ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~ ~
## S4 method for signature 'DelayedUnaryIsoOpWithArgs'
is_sparse(x)

## S4 method for signature 'DelayedUnaryIsoOpWithArgs'
exttract_sparse_array(x, index)
```

Arguments

- **x**, object: A DelayedUnaryIsoOpWithArgs object.
- **index**: See `?extract_array` for a description of the index argument.
- **...**: Not used.
Details

A DelayedUnaryIsoOpWithArgs object is used to represent the delayed version of an operation of the form:

\[ \text{out} \leftarrow \text{OP}(L1, L2, \ldots, a, R1, R2, \ldots) \]

where:

- **OP** is an isometric array transformation i.e. a transformation that returns an array with the same dimensions as the input array.
- **a** is the input array.
- **L1, L2, etc...** are the left arguments.
- **R1, R2, etc...** are the right arguments.
- The output (out) is an array of same dimensions as **a**.

Some of the arguments (left or right) can go along the dimensions of the input array. For example if **a** is a 12 x 150 x 5 array, argument **L2** is considered to go along the 3rd dimension if its length is 5 and if the result of:

\[ \text{OP}(L1, L2[k], \ldots, a[, , k, \text{drop=FALSE}], R1, R2, \ldots) \]

is the same as \[ out[, , k, \text{drop=FALSE}] \] for any index \( k \).

More generally speaking, if, say, arguments \( L2, L3, R1, \) and \( R2 \) go along the 3rd, 1st, 2nd, and 1st dimensions, respectively, then each value in the output array \( \text{a}[i,j,k] \) must be determined solely by the corresponding values in the input array \( \text{a}[i,j,k] \) and arguments \( \text{L2}[k], \text{L3}[i], \text{R1}[j], \text{R2}[i] \). In other words, \( \text{out}[i,j,k] \) must be equal to:

\[ \text{OP}(L1, L2[k], L3[i], \ldots, \text{a}[i, j, k], R1[j], R2[i], \ldots) \]

for any \( 1 \leq i \leq 12, 1 \leq j \leq 150, \) and \( 1 \leq k \leq 5. \)

We refer to this property as the *locality principle*.

Concrete examples:

1. Addition (or any operation in the **Ops** group) of an array **a** and an atomic vector **v** of length \( \text{dim}(\text{a})[[1]] \):
   - `+` \( (a,v) \): **OP** is `+`, right argument goes along the 1st dimension.
   - `<=` \( (a,v) \): **OP** is `<=`, right argument goes along the 1st dimension.
   - `&` \( (v,a) \): **OP** is `&`, left argument goes along the 1st dimension.

2. `scale(x,center=v1,scale=v2)`: **OP** is `scale`, right arguments `center` and `scale` go along the 2nd dimension.

Note that if **OP** has no argument that goes along a dimension of the input array, then the delayed operation is better represented with a **DelayedUnaryIsoOpStack** object.

makeCappedVolumeBox

Utilities to make capped volume boxes

Description

makeCappedVolumeBox returns the dimensions of the biggest multidimensional box (a.k.a. hyper-rectangle) that satisfies 3 constraints: (1) its volume is capped, (2) it fits in the constraining box, (3) it has the specified shape.

makeRegularArrayGridOfCappedLengthViewports makes a RegularArrayGrid object with grid elements that are capped volume boxes with the specified constraints.

These are low-level utilities used internally to support defaultAutoGrid and family.

Usage

makeCappedVolumeBox(maxvol, maxdim, shape=c("hypercube", "scale", "first-dim-grows-first", "last-dim-grows-first"))

makeRegularArrayGridOfCappedLengthViewports(refdim, viewport_len, viewport_shape=c("hypercube", "scale", "first-dim-grows-first", "last-dim-grows-first"))

Arguments

maxvol The maximum volume of the box to return.
maxdim The dimensions of the constraining box.
shape The shape of the box to return.
refdim The dimensions of the reference array of the grid to return.
viewport_len The maximum length of the elements (a.k.a. viewports) of the grid to return.
viewport_shape The shape of the elements (a.k.a. viewports) of the grid to return.
Details

makeCappedVolumeBox returns the dimensions of a box that satisfies the following constraints:

1. The volume of the box is as close as possible to (but no bigger than) maxvol.
2. The box fits in the constraining box i.e. in the box whose dimensions are specified via maxdim.
3. The box has a non-zero volume if the constraining box has a non-zero volume.
4. The shape of the box is as close as possible to the requested shape.

The supported shapes are:

• hypercube: The box should be as close as possible to an hypercube (a.k.a. n-cube), that is, the ratio between its biggest and smallest dimensions should be as close as possible to 1.
• scale: The box should have the same proportions as the constraining box.
• first-dim-grows-first: The box will be grown along its 1st dimension first, then along its 2nd dimension, etc...
• last-dim-grows-first: Like first-dim-grows-first but starting along the last dimension.

See Also

• defaultAutoGrid and family to create automatic grids to use for block processing of array-like objects.
• ArrayGrid for the formal representation of grids and viewports.

Examples

```r
## ---------------------------------------------------------------------
## makeCappedVolumeBox()
## ---------------------------------------------------------------------

maxdim <- c(50, 12)  # dimensions of the "constraining box"

## "hypercube" shape:
makeCappedVolumeBox(40, maxdim)
makeCappedVolumeBox(120, maxdim)
makeCappedVolumeBox(125, maxdim)
makeCappedVolumeBox(200, maxdim)

## "scale" shape:
makeCappedVolumeBox(40, maxdim, shape="scale")
makeCappedVolumeBox(160, maxdim, shape="scale")

## "first-dim-grows-first" and "last-dim-grows-first" shapes:
makeCappedVolumeBox(120, maxdim, shape="first-dim-grows-first")
makeCappedVolumeBox(149, maxdim, shape="first-dim-grows-first")
makeCappedVolumeBox(150, maxdim, shape="first-dim-grows-first")
makeCappedVolumeBox(40, maxdim, shape="last-dim-grows-first")
makeCappedVolumeBox(59, maxdim, shape="last-dim-grows-first")
```
makeCappedVolumeBox(60, maxdim, shape="last-dim-grows-first")

## ---------------------------------------------------------------------
## makeRegularArrayGridOfCappedLengthViewports()
## ---------------------------------------------------------------------

grid1a <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 40)
grid1a
as.list(grid1a) # turn the grid into a list of ArrayViewport objects
table(lengths(grid1a))
stopifnot(maxlength(grid1a) <= 40) # sanity check

grid1b <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 40, "first-dim-grows-first")
gird1b
as.list(grid1b) # turn the grid into a list of ArrayViewport objects
table(lengths(grid1b))
stopifnot(maxlength(grid1b) <= 40) # sanity check

grid2a <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 120)
gird2a
as.list(grid2a) # turn the grid into a list of ArrayViewport objects
table(lengths(grid2a))
stopifnot(maxlength(grid2a) <= 120) # sanity check

grid2b <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 120, "first-dim-grows-first")
grid2b
as.list(grid2b) # turn the grid into a list of ArrayViewport objects
table(lengths(grid2b))
stopifnot(maxlength(grid2b) <= 120) # sanity check

grid3a <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 200)
gird3a
as.list(grid3a) # turn the grid into a list of ArrayViewport objects
table(lengths(grid3a))
stopifnot(maxlength(grid3a) <= 200) # sanity check

grid3b <- makeRegularArrayGridOfCappedLengthViewports(maxdim, 200, "first-dim-grows-first")
gird3b
as.list(grid3b) # turn the grid into a list of ArrayViewport objects
table(lengths(grid3b))
stopifnot(maxlength(grid3b) <= 200) # sanity check
Description

Use `read_block` to read a block from an array-like object. The function is typically used in the context of block processing of array-like objects (typically `DelayedArray` objects but not necessarily).

Usage

```
read_block(x, viewport, as.sparse=FALSE)
```

Arguments

- `x`: An array-like object, typically a `DelayedArray` object or derivative.
- `viewport`: An `ArrayViewport` object compatible with `x`, that is, such that `refdim(viewport)` is identical to `dim(x)`.
- `as.sparse`: Can be `FALSE`, `TRUE`, or `NA`. If `FALSE` (the default), the block is returned as an ordinary array (a.k.a. dense array). If `TRUE`, it's returned as a `SparseArraySeed` object. Using `as.sparse=NA` is equivalent to using `as.sparse=is_sparse(x)` and is the most efficient way to read a block. (This might become the default in the future.) Note that when returned as a 2D `SparseArraySeed` object with numeric or logical data, a block can easily and efficiently be coerced to a `sparseMatrix` derivative from the `Matrix` package with `as(block,"sparseMatrix")`. This will return a `dgCMatrix` object if `type(block)` is "double" or "integer", or a `lgCMatrix` object if it's "logical".

Value

The data from `x` that belongs to the block delimited by the specified viewport. The data is returned as an ordinary (dense) array or as a `SparseArraySeed` object. In both cases it has the same dimensions as the `viewport`.

See Also

- `ArrayViewport` objects.
- `SparseArraySeed` objects.
- `write_block`.
- `blockApply` and family for convenient block processing of an array-like object.
- `defaultAutoGrid` and family to create automatic grids to use for block processing of array-like objects.
- `dgCMatrix-class` and `lgCMatrix-class` objects in the `Matrix` package.
- `DelayedArray` objects.
- `array` objects in base R.
read_block

Examples

```r
## TYPICAL USE
# read_block() is typically used in combination with write_block().
# See '?write_block' for typical uses of the read_block/write_block combo.

## VERY BASIC (BUT ALSO VERY ARTIFICIAL) EXAMPLE 1:
# Read a block from an ordinary matrix
m1 <- matrix(1:30, ncol=5)
m1

## Define the viewport on m1 to read the data from:
block1_dim <- c(4, 3)
viewport1 <- ArrayViewport(dim(m1), IRanges(c(3, 2), width=block1_dim))
viewport1

## Read the block:
block1 <- read_block(m1, viewport1) # same as m1[3:6, 2:4, drop=FALSE]
block1

## Sanity checks:
stopifnot(identical(dim(viewport1), dim(block1)))
stopifnot(identical(m1[3:6, 2:4, drop=FALSE], block1))

## VERY BASIC (BUT ALSO VERY ARTIFICIAL) EXAMPLE 2:
# Read a block from a sparse matrix
m2 <- rsparsematrix(12, 20, density=0.2,
rand.x=function(n) sample(25, n, replace=TRUE))
m2

## Define the viewport on m2 to read the data from:
block2_dim <- c(2, 20)
viewport2 <- ArrayViewport(dim(m2), IRanges(c(1, 1), width=block2_dim))
viewport2

## By default, read_block() always returns an ordinary matrix or array:
block2 <- read_block(m2, viewport2) # same as m2[1:2, 1:20, drop=FALSE]
block2

## It is recommended to use 'as.sparse=NA' rather than 'as.sparse=TRUE'
## or 'as.sparse=FALSE' to let read_block() pick up the optimal
## representation:
block2b <- read_block(m2, viewport2, as.sparse=NA)
class(block2b) # a SparseArraySeed object
as(block2b, "sparseMatrix")
```
realize

Realize a DelayedArray object

Description
Realize a DelayedArray object in memory or on disk.

Usage
realize(x, ...)

## S4 method for signature 'ANY'
realize(x, BACKEND=getAutoRealizationBackend())

Arguments

x
The array-like object to realize.

... Additional arguments passed to methods.
**RleArray-class**

**Value**

A single string specifying the name of the realization backend. Use the current automatic realization backend by default i.e. the backend returned by `getAutoRealizationBackend()`.

**See Also**

- `getAutoRealizationBackend` and `setAutoRealizationBackend` for getting and setting the current automatic realization backend.
- `DelayedArray` objects.
- `RleArray` objects.
- `HDF5Array` objects in the `HDF5Array` package.
- `array` objects in base R.

**Examples**

```r
library(HDF5Array)
toy_h5 <- system.file("extdata", "toy.h5", package="HDF5Array")
h5ls(toy_h5)
M1 <- HDF5Array(toy_h5, "M1")
M2 <- HDF5Array(toy_h5, "M2")
M3 <- rbind(log(M1), t(M2))

supportedRealizationBackends()
getAutoRealizationBackend() # backend is set to NULL
realize(M3) # realization as ordinary array

setAutoRealizationBackend("RleArray")
getAutoRealizationBackend() # backend is set to "RleArray"
realize(M3) # realization as RleArray object

setAutoRealizationBackend("HDF5Array")
getAutoRealizationBackend() # backend is set to "HDF5Array"
realize(M3) # realization in HDF5 file
```

**Description**

The `RleArray` class is a `DelayedArray` subclass for representing an in-memory Run Length Encoded array-like dataset.

All the operations available for `DelayedArray` objects work on `RleArray` objects.
Usage

## Constructor function:
RleArray(data, dim, dimnames, chunksize=NULL)

Arguments

data An Rle object, or an ordinary list of Rle objects, or an RleList object, or a DataFrame object where all the columns are Rle objects. More generally speaking, data can be any list-like object where all the list elements are Rle objects.
dim The dimensions of the object to be created, that is, an integer vector of length one or more giving the maximal indices in each dimension.
dimnames The dimnames of the object to be created. Must be NULL or a list of length the number of dimensions. Each list element must be either NULL or a character vector along the corresponding dimension.
chunksize Experimental. Don’t use!

Value

An RleArray (or RleMatrix) object. (Note that RleMatrix extends RleArray.)

See Also

• Rle and DataFrame objects in the S4Vectors package and RleList objects in the IRanges package.
• DelayedArray objects.
• DelayedArray-utils for common operations on DelayedArray objects.
• realize for realizing a DelayedArray object in memory or on disk.
• ConstantArray objects for mimicking an array containing a constant value, without actually creating said array in memory.
• HDF5Array objects in the HDF5Array package.
• The RleArraySeed helper class.

Examples

## BASIC EXAMPLE

```
data <- Rle(sample(6L, 500000, replace=TRUE), 8)
a <- array(data, dim=c(50, 20, 4000))  # array() expands the Rle object
# internally with as.vector()

A <- RleArray(data, dim=c(50, 20, 4000))  # Rle object is NOT expanded
A

object.size(a)
object.size(A)
```
stopifnot(identical(a, as.array(A)))

as(A, "Rle") # deconstruction

toto <- function(x) (5 * x[, 1] ^ 3 + 1L) * log(x[, 2])
m1 <- toto(a)
head(m1)

M1 <- toto(A) # very fast! (operations are delayed)
M1

stopifnot(identical(m1, as.array(M1)))

cs <- colSums(m1)
CS <- colSums(M1)
stopifnot(identical(cs, CS))

## Coercing a DelayedMatrix object to DataFrame produces a DataFrame
## object with Rle columns:
as(M1, "DataFrame")

## B. MAKING AN RleArray OBJECT FROM A LIST-LIKE OBJECT OF Rle OBJECTS
## ---------------------------------------------------------------------

## From a DataFrame object:
DF <- DataFrame(A=Rle(sample(3L, 100, replace=TRUE)),
               B=Rle(sample(3L, 100, replace=TRUE)),
               C=Rle(sample(3L, 100, replace=TRUE) - 0.5),
               row.names=sprintf("ID%03d", 1:100))

M2 <- RleArray(DF)
M2

A3 <- RleArray(DF, dim=c(25, 6, 2))
A3

M4 <- RleArray(DF, dim=c(25, 12), dimnames=list(LETTERS[1:25], NULL))
M4

## From an ordinary list:
## If all the supplied Rle objects have the same length and if the 'dim'
## argument is not specified, then the RleArray() constructor returns an
## RleMatrix object with 1 column per Rle object. If the 'dimnames'
## argument is not specified, then the names on the list are propagated
## as the colnames of the returned object.
data <- as.list(DF)
M2b <- RleArray(data)
A3b <- RleArray(data, dim=c(25, 6, 2))
M4b <- RleArray(data, dim=c(25, 12), dimnames=list(LETTERS[1:25], NULL))
data2 <- list(Rle(sample(3L, 9, replace=TRUE)) * 11L,
```R
Rle(sample(3L, 15, replace=TRUE))
## Not run:
RleArray(data2) # error! (cannot infer the dim)
## End(Not run)
RleArray(data2, dim=c(4, 6))

## From an RleList object:
data <- RleList(data)
M2c <- RleArray(data)
A3c <- RleArray(data, dim=c(25, 6, 2))
M4c <- RleArray(data, dim=c(25, 12), dimnames=list(LETTERS[1:25], NULL))
data2 <- RleList(data2)
## Not run:
RleArray(data2) # error! (cannot infer the dim)
## End(Not run)
RleArray(data2, dim=4:2)

## Sanity checks:
data0 <- as.vector(unlist(DF, use.names=FALSE))
m2 <- matrix(data0, ncol=3, dimnames=dimnames(M2))
stopifnot(identical(m2, as.matrix(M2)))
rownames(m2) <- NULL
stopifnot(identical(m2, as.matrix(M2b)))
stopifnot(identical(m2, as.matrix(M2c)))
a3 <- array(data0, dim=c(25, 6, 2))
stopifnot(identical(a3, as.array(A3)))
stopifnot(identical(a3, as.array(A3b)))
stopifnot(identical(a3, as.array(A3c)))
m4 <- matrix(data0, ncol=12, dimnames=dimnames(M4))
stopifnot(identical(m4, as.matrix(M4)))
stopifnot(identical(m4, as.matrix(M4b)))
stopifnot(identical(m4, as.matrix(M4c)))

# C. COERCING FROM RleList OR DataFrame TO RleMatrix
#
## Coercing an RleList object to RleMatrix only works if all the list
## elements in the former have the same length.
x <- RleList(A=Rle(sample(3L, 20, replace=TRUE)),
             B=Rle(sample(3L, 20, replace=TRUE)))
M <- as(x, "RleMatrix")
stopifnot(identical(x, as(M, "RleList")))

x <- DataFrame(A=x[[1]], B=x[[2]], row.names=letters[1:20])
M <- as(x, "RleMatrix")
stopifnot(identical(x, as(M, "DataFrame")))

# D. CONSTRUCTING A LARGE RleArray OBJECT
```

## The RleArray() constructor does not accept a "long" Rle object (i.e.
an object of length > .Machine$integer.max) at the moment:
## Not run:
RleArray(Rle(5, 3e9), dim=c(3, 1e9)) # error!
## End(Not run)
## The workaround is to supply a list of Rle objects instead:

toy_Rle <- function() {
  run_lens <- c(sample(4), sample(rep(c(1:19, 40) * 3, 6e4)), sample(4))
  run_vals <- sample(700, length(run_lens), replace=TRUE) / 5
  Rle(run_vals, run_lens)
}

toy_Rle <- lapply(1:80, function(j) toy_Rle()) # takes about 20 sec.

cumulative length of all the Rle objects is > .Machine$integer.max:
sum(lengths(toy_Rle)) # 3.31e+09
## Feed 'rle_list' to the RleArray() constructor:
dim <- c(14395, 320, 719)
A <- RleArray(rle_list, dim)
A
## Because all the Rle objects in 'rle_list' have the same length, we
can call RleArray() on it without specifying the 'dim' argument. This
## returns an RleMatrix object where each column corresponds to an Rle
## object in 'rle_list':
M <- RleArray(rle_list)
M
stopifnot(identical(as(rle_list, "RleList"), as(M, "RleList"))

## E. CHANGING THE TYPE OF AN RleArray OBJECT FROM "double" TO "integer"
##
## An RleArray object is an in-memory object so it can be useful to
## reduce its memory footprint. For an object of type "double" this can
## be done by changing its type to "integer" (integers are half the size
## of doubles in memory). Of course this only makes sense if this results
## in a loss of precision that is acceptable.
## On an ordinary array (or matrix) 'a', this is simply a matter of
## doing 'storage.mode(a) <- "integer"'. However, with a DelayedArray
## object, things are a little bit different. Let's do this on a subset
## of the RleMatrix object 'M' created in the previous section.

M1 <- as(M[1:6e5, ], "RleMatrix")
rm(M)
## First of all, it's important to be aware that object.size() (from
## package utils) is NOT reliable on RleArray objects! This is because
## the data in an RleArray object is stored in an environment and
## object.size() stubbornly refuses to take the content of an environment
## into account when computing its size:
object.size(list2env(list(aa=1:10))) # 56 bytes
object.size(list2env(list(aa=1:1e6))) # always 56 bytes!

## So we'll use obj_size() instead (from package lobstr):
library(lobstr)
obj_size(list2env(list(aa=1:10))) # 264 B
obj_size(list2env(list(aa=1:1e6))) # 4 MB
obj_size(list2env(list(aa=as.double(1:1e6)))) # 8 MB

obj_size(M1) # 16.7 MB

type(M1) <- "integer" # Delayed!
M1 # Note the class: it's no longer RleMatrix!
  # (That's because the object now carries delayed
  # operations.)

## Because changing the type is a delayed operation, the memory footprint
## of the object has not changed yet (remember that the original data in
## a DelayedArray object is stored in its "seed" and its seed is never
## modified **in-place**, that is, no operation on the object will ever
## modify its seed):
obj_size(M1) # Still the same (well, a very tiny more, because the
# object is now carrying one more delayed operation,
# the `type<-` operation)

## To effectively reduce the memory footprint of the object, a new object
## needs to be created. This is achieved simply by **realizing** M1 as a
## (new) RleArray object. Note that this realization will use block
## processing:

DelayedArray:::set_verbose_block_processing(TRUE) # See block processing
  # in action.
getAutoBlockSize() # Automatic block size (100 Mb by default).
setAutoBlockSize(20e6) # Set automatic block size to 20 Mb.

M2 <- as(M1, "RleArray")
DelayedArray:::set_verbose_block_processing(FALSE)
setAutoBlockSize() # Reset automatic block size to factory settings.

M2

obj_size(M2) # 6.91 MB (Less than half the original size! This is
# because RleArray objects use some internal tricks to
# reduce memory footprint even more when the data in
# their seed is of type "integer".)

## Finally note that the 2-step approach described here (i.e.
## type(A) <- "integer" followed by realization) is generic and works
## on any kind of DelayedArray object or derivative. In particular,
## after doing 'type(A) <- "integer"', 'A' can be realized as anything
## as long as the realization backend is supported (e.g. could be
## `as(A, "HDF5Array")` or `as(A, "TENxMatrix")`) and realization will
## always use block processing so the array data will never be fully
## loaded in memory.

### RleArraySeed-class  RleArraySeed objects

**Description**

RleArraySeed is a low-level helper class for representing an in-memory Run Length Encoded array-like dataset. RleArraySeed objects are not intended to be used directly. Most end users should create and manipulate RleArray objects instead. See ?RleArray for more information.

**Details**

No operation can be performed directly on an RleArraySeed object. It first needs to be wrapped in a DelayedArray object. The result of this wrapping is an RleArray object (an RleArray object is just an RleArraySeed object wrapped in a DelayedArray object).

**See Also**

- RleArray objects.
- Rle objects in the S4Vectors package.

### showtree

**Visualize and access the leaves of a tree of delayed operations**

**Description**

showtree can be used to visualize the tree of delayed operations carried by a DelayedArray object. Use nseed, seed, or path to access the number of seeds, the seed, or the seed path of a DelayedArray object, respectively.

Use seedApply to apply a function to the seeds of a DelayedArray object.

**Usage**

```
showtree(x, show.node.dim=TRUE)
nseed(x)  # seed counter
seed(x)   # seed getter and setter
path(object, ...)  # path getter and setter
seedApply(x, FUN, ...)
```
showtree

Arguments

- **x, object**: Typically a `DelayedArray` object but can also be a `DelayedOp` object or a list where each element is a `DelayedArray` or `DelayedOp` object.
- **show.node.dim**: TRUE or FALSE. If TRUE (the default), the nodes dimensions and data type are displayed.
- **FUN**: The function to be applied to each leaf in `x`.
- **...**: Optional arguments to FUN for `seedApply()`.
  Additional arguments passed to methods for `path()`.

Value

- The number of seeds contained in `x` for `nseed`.
- The seed contained in `x` for `seed`.
- The path of the seed contained in `object` for `path`.
- A list of length `nseed(x)` for `seedApply`.

See Also

- `simplify` to simplify the tree of delayed operations carried by a `DelayedArray` object.
- `DelayedOp` objects.
- `DelayedArray` objects.

Examples

```r
# showtree(), nseed(), and seed()
#-------------------------------------------------------------
m1 <- matrix(runif(150), nrow=15, ncol=10)
M1 <- DelayedArray(m1)
showtree(M1)
seed(M1)

M2 <- log(t(M1[5:1, c(TRUE, FALSE)] + 10))[-1,]
showtree(M2)

# In the above example, the tree is linear i.e. all the operations
# are represented by unary nodes. The simplest way to know if a
# tree is linear is by counting its leaves with nseed():
# nseed(M2) # only 1 leaf means the tree is linear
seed(M2)

dimnames(M1) <- list(letters[1:15], LETTERS[1:10])
showtree(M1)

m2 <- matrix(1:20, nrow=10)
Y <- cbind(t(M1[, 10:1]), DelayedArray(m2), M1[6:15, "A", drop=FALSE])
showtree(Y)
showtree(Y, show.node.dim=FALSE)
```
simplify

\[ \text{nseed}(Y) \quad \# \text{the tree is not linear} \]
\[ Z \leftarrow t(Y[1:15,]) + 0.4 \cdot M1 \]
\[ \text{showtree}(Z) \]
\[ \text{nseed}(Z) \quad \# \text{the tree is not linear} \]

## ---------------------------------------------------------------------
## seedApply()
## ---------------------------------------------------------------------
\[ \text{seedApply}(Y, \text{class}) \]
\[ \text{seedApply}(Y, \text{dim}) \]

---

**simplify**

*Simplify a tree of delayed operations*

**Description**

NOTE: The tools documented in this man page are primarily intended for developers or advanced users curious about the internals of the `DelayedArray` package. End users typically don’t need them for their regular use of `DelayedArray` objects.

In a `DelayedArray` object, the delayed operations are stored as a tree of `DelayedOp` objects. See `?DelayedOp` for more information about this tree.

`simplify` can be used to simplify the tree of delayed operations in a `DelayedArray` object.

`isPristine` can be used to know whether a `DelayedArray` object is *pristine* or not. A `DelayedArray` object is considered *pristine* when it carries no delayed operation. Note that an object that carries delayed operations that do nothing (e.g. `A + 0`) is not considered *pristine*.

`contentIsPristine` can be used to know whether the delayed operations in a `DelayedArray` object touch its array elements or not.

`netSubsetAndAperm` returns an object that represents the *net subsetting* and *net dimension rearrangement* of all the delayed operations in a `DelayedArray` object.

**Usage**

\[ \text{simplify}(x, \text{incremental}=\text{FALSE}) \]
\[ \text{isPristine}(x, \text{ignore.dimnames}=\text{FALSE}) \]
\[ \text{contentIsPristine}(x) \]
\[ \text{netSubsetAndAperm}(x, \text{as.DelayedOp}=\text{FALSE}) \]

**Arguments**

- **x**: Typically a `DelayedArray` object but can also be a `DelayedOp` object (except for `isPristine`).
- **incremental**: For internal use.
ignore.dimnames

TRUE or FALSE. When TRUE, the object is considered pristine even if its dimnames have been modified and no longer match the dimnames of its seed (in which case the object carries a single delayed operations of type DelayedSetDimnames).

as.DelayedOp

TRUE or FALSE. Controls the form of the returned object. See details below.

Details

netSubsetAndAperm is only supported on a DelayedArray object x with a single seed i.e. if nseed(x) == 1.

The mapping between the array elements of x and the array elements of its seed is affected by the following delayed operations carried by x: [ , drop() , and aperm(). x can carry any number of each of these operations in any order but their net result can always be described by a net subsetting followed by a net dimension rearrangement.

netSubsetAndAperm(x) returns an object that represents the net subsetting and net dimension rearrangement. The as.DelayedOp argument controls in what form this object should be returned:

- If as.DelayedOp is FALSE (the default), the returned object is a list of subscripts that describes the net subsetting. The list contains one subscript per dimension in the seed. Each subscript can be either a vector of positive integers or a NULL. A NULL indicates a missing subscript. In addition, if x carries delayed operations that rearrange its dimensions (i.e. operations that drop and/or permute some of the original dimensions), the net dimension rearrangement is described in a dimmap attribute added to the list. This attribute is an integer vector parallel to dim(x) that reports how the dimensions of x are mapped to the dimensions of its seed.

- If as.DelayedOp is TRUE, the returned object is a linear tree with 2 DelayedOp nodes and a leaf node. The leaf node is the seed of x. Walking the tree from the seed, the 2 DelayedOp nodes are of type DelayedSubset and DelayedAperm, in that order (this reflects the order in which the operations apply). More precisely, the returned object is a DelayedAperm object with one child (the DelayedSubset object), and one grandchild (the seed of x). The DelayedSubset and DelayedAperm nodes represent the net subsetting and net dimension rearrangement, respectively. Either or both of them can be a no-op.

Note that the returned object describes how the array elements of x map to their corresponding array element in seed(x).

Value

The simplified object for simplify.

TRUE or FALSE for contentIsPristine.

An ordinary list (possibly with the dimmap attribute on it) for netSubsetAndAperm. Unless as.DelayedOp is set to TRUE, in which case a DelayedAperm object is returned (see Details section above for more information).

See Also

- showtree to visualize and access the leaves of a tree of delayed operations carried by a DelayedArray object.
• DelayedOp objects.
  • DelayedArray objects.

Examples

## ---------------------------------------------------------------
## Simplification of the tree of delayed operations
## ---------------------------------------------------------------
m1 <- matrix(runif(150), nrow=15, ncol=10)
M1 <- DelayedArray(m1)
showtree(M1)

## By default, the tree of delayed operations carried by a DelayedArray
## object gets simplified each time a delayed operation is added to it.
## This can be disabled via a global option:
options(DelayedArray.simplify=FALSE)
M2 <- log(t(M1[5:1, c(TRUE, FALSE)] + 10))[-1, ]
showtree(M2) # linear tree

## Note that as part of the simplification process, some operations
## can be reordered:
options(DelayedArray.simplify=TRUE)
M2 <- log(t(M1[5:1, c(TRUE, FALSE)] + 10))[-1, ]
showtree(M2) # linear tree

ooptions(DelayedArray.simplify=FALSE)
dimnames(M1) <- list(letters[1:15], LETTERS[1:10])
showtree(M1) # linear tree

m2 <- matrix(1:20, nrow=10)
Y <- cbind(t(M1[, 10:1]), DelayedArray(m2), M1[6:15, "A", drop=FALSE])
showtree(Y) # non-linear tree

Z <- t(Y[10:1, ])[1:15, ] + 0.4 * M1
showtree(Z) # non-linear tree

Z@seed@seeds
Z@seed@seeds[[2]]@seed # reaching to M1
Z@seed@seeds[[1]]@seed@seed@seed@seed@seed # reaching to Y

## ---------------------------------------------------------------
## isPristine()
## ---------------------------------------------------------------

**SparseArraySeed-class**  
**SparseArraySeed objects**

**Description**

SparseArraySeed objects are used internally to support block processing of array-like objects.

**Usage**

```r
## Constructor function:
SparseArraySeed(dim, nzindex=NULL, nzdata=NULL, dimnames=NULL, check=TRUE)
```

```r
## Getters (in addition to dim(), length(), and dimnames()):
nzindex(x)
nzdata(x)
sparsity(x)
```

```r
## Two low-level utilities:
dense2sparse(x)
sparse2dense(sas)
```

**Arguments**

- **dim**
  - The dimensions (specified as an integer vector) of the SparseArraySeed object to create.

- **nzindex**
  - A matrix containing the array indices of the nonzero data.
  
    This must be an integer matrix like one returned by `base::arrayInd`, that is, with `length(dim)` columns and where each row is an n-uplet representing an array index.
SparseArraySeed-class

nzdata
A vector (atomic or list) of length nrow(nzindex) containing the nonzero data.

dimnames
The dimnames of the object to be created. Must be NULL or a list of length the number of dimensions. Each list element must be either NULL or a character vector along the corresponding dimension.

check
Should the object be validated upon construction?

x
A SparseArraySeed object for the nzindex, nzdata, and sparsity getters.
An array-like object for dense2sparse.

sas
A SparseArraySeed object.

Value
- For SparseArraySeed(): A SparseArraySeed instance.
- For nzindex(): The matrix containing the array indices of the nonzero data.
- For nzdata(): The vector of nonzero data.
- For sparsity(): The number of zero-valued elements in the implicit array divided by the total number of array elements (a.k.a. the length of the array).
- For dense2sparse(): A SparseArraySeed instance.
- For sparse2dense(): An ordinary array.

See Also
- SparseArraySeed-utils for native operations on SparseArraySeed objects.
- S4 classes dgCMatrix, dgRMatrix, and lsparseMatrix, defined in the Matrix package, for the de facto standard of sparse matrix representations in R.
- The read_block function.
- blockApply and family for convenient block processing of an array-like object.
- extract_array.
- DelayedArray objects.
- arrayInd in the base package.
- array objects in base R.

Examples

```r
## EXAMPLE 1

dim1 <- 5:3
nzindex1 <- Lindex2Mindex(sample(60, 8), 5:3)
nzdata1 <- 11.11 * seq_len(nrow(nzindex1))
sas1 <- SparseArraySeed(dim1, nzindex1, nzdata1)

dim(sas1) # the dimensions of the implicit array
length(sas1) # the length of the implicit array
nzindex(sas1)
nzdata(sas1)
```
SparseArraySeed-class

```
type(sas1)
sparsity(sas1)

sparse2dense(sas1)
as.array(sas1)  # same as sparse2dense(sas1)

## Not run:
as.matrix(sas1)  # error!
## End(Not run)

## EXAMPLE 2

m2 <- matrix(c(5:-2, rep.int(c(0L, 99L), 11)), ncol=6)
sas2 <- dense2sparse(m2)
class(sas2)
dim(sas2)
length(sas2)
nzindex(sas2)
nzdata(sas2)
type(sas2)
sparsity(sas2)

stopifnot(identical(sparse2dense(sas2), m2))
as.matrix(sas2)  # same as sparse2dense(sas2)

t(sas2)
stopifnot(identical(as.matrix(t(sas2)), t(as.matrix(sas2))))

## COERCION FROM/TO dgC|R|Matrix OR lgC|R|Matrix OBJECTS

dgC|R|Matrix and lgC|R|Matrix objects are defined in the Matrix package.

dgCMatrix/dgRMatrix:

M2C <- as(sas2, "dgCMatrix")
stopifnot(identical(M2C, as(m2, "dgCMatrix")))
sas2C <- as(M2C, "SparseArraySeed")

'sas2C' is the same as 'sas2' except that 'nzdata(sas2C)' has
"double" instead of "integer":

stopifnot(all.equal(sas2, sas2C))
typeof(nzdata(sas2C))  # double
typeof(nzdata(sas2))  # integer

M2R <- as(sas2, "dgRMatrix")
stopifnot(identical(M2R, as(m2, "dgRMatrix")))
sas2R <- as(M2R, "SparseArraySeed")
stopifnot(all.equal(as.matrix(sas2), as.matrix(sas2R)))
```
## lgCMatrix/lgRMatrix:

```r
m3 <- m2 == 99  # logical matrix
sas3 <- dense2sparse(m3)
class(sas3)
type(sas3)

M3C <- as(sas3, "lgCMatrix")
stopifnot(identical(M3C, as(m3, "lgCMatrix")))
sas3C <- as(M3C, "SparseArraySeed")
identical(as.matrix(sas3), as.matrix(sas3C))

M3R <- as(sas3, "lgRMatrix")
#stopifnot(identical(M3R, as(m3, "lgRMatrix")))
sas3R <- as(M3R, "SparseArraySeed")
identical(as.matrix(sas3), as.matrix(sas3R))
```

## SEED CONTRACT

**SparseArraySeed objects comply with the "seed contract".**

In particular they support `extract_array()`:

```r
extract_array(sas1, list(c(5, 3:2, 5), NULL, 3))
```

This means that they can be wrapped in a `DelayedArray` object:

```r
A1 <- DelayedArray(sas1)
A1
```

A big very sparse `DelayedMatrix` object:

```r
nzindex4 <- cbind(sample(25000, 600000, replace=TRUE),
                  sample(195000, 600000, replace=TRUE))
.nzdata4 <- runif(600000)
sas4 <- SparseArraySeed(c(25000, 195000), nzindex4, nzdata4)
sparsity(sas4)

M4 <- DelayedArray(sas4)
M4
colSums(M4[, 1:20])
```

---

**Operate natively on SparseArraySeed objects**

**Description**

Some utilities to operate natively on `SparseArraySeed` objects. Mostly for internal use by the `DelayedArray` package e.g. they support block processed methods for sparse `DelayedArray` objects like `sum()`, `mean()`, `which()`, etc...
Usage

## S4 method for signature 'SparseArraySeed'
is.na(x)

## S4 method for signature 'SparseArraySeed'
is.infinite(x)

## S4 method for signature 'SparseArraySeed'
is.nan(x)

## S4 method for signature 'SparseArraySeed'
tolower(x)

## S4 method for signature 'SparseArraySeed'
toupper(x)

## S4 method for signature 'SparseArraySeed'
nchar(x, type="chars", allowNA=FALSE, keepNA=NA)

## S4 method for signature 'SparseArraySeed'
anyNA(x, recursive=FALSE)

## S4 method for signature 'SparseArraySeed'
which(x, arr.ind=FALSE, useNames=TRUE)

## <-<-<>-<> "Summary" group generic <-<-<>-<>

## S4 method for signature 'SparseArraySeed'
max(x, ..., na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
min(x, ..., na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
range(x, ..., finite=FALSE, na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
sum(x, ..., na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
prod(x, ..., na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
any(x, ..., na.rm=FALSE)

## S4 method for signature 'SparseArraySeed'
all(x, ..., na.rm=FALSE)
## S4 method for signature 'SparseArraySeed' 

mean(x, na.rm=FALSE)

### Arguments

- **x**: A SparseArraySeed object.
- **type**, **allowNA**, **keepNA**: See ?base::nchar for a description of these arguments.
- **recursive**: See ?base::anyNA for a description of this argument.
- **arr.ind**: See ?base::which for a description of this argument.
- **useNames**: Ignored.
- **...**: Unsupported.
- **na.rm**: TRUE or FALSE (the default). Should NA’s and NaN’s be removed?
- **finite**: TRUE or FALSE (the default). Should non-finite values be removed?

### Value

See corresponding functions in the base package.

### See Also

- SparseArraySeed objects.

### Examples

```r
## Create a SparseArraySeed object:
dim1 <- 5:3
nzindex1 <- Lindex2Mindex(sample(60, 14), 5:3)
sas1 <- SparseArraySeed(dim1, nzindex1, nzdata=sample(0:13))

## Apply native operations:
sum(sas1)
range(sas1)
mean(sas1)

## Sanity checks:
stopifnot(identical(sum(as.array(sas1)), sum(sas1)))
stopifnot(identical(range(as.array(sas1)), range(sas1)))
stopifnot(identical(mean(as.array(sas1)), mean(sas1)))
```
Description

Some utilities to operate natively on sparseMatrix objects (e.g. dgCMatrix and lgCMatrix objects) from the Matrix package. Mostly for internal use by the DelayedArray package.

Usage

```r
## rowsum() and colsum() S4 generics:
#rowsum(x, group, reorder=TRUE, ...)
#colsum(x, group, reorder=TRUE, ...)

## Default methods:
## S4 method for signature 'ANY'
rowsum(x, group, reorder=TRUE, ...)
## S4 method for signature 'ANY'
colsum(x, group, reorder=TRUE, ...)

## rowsum() method for dgCMatrix objects:
## S4 method for signature 'dgCMatrix'
rowsum(x, group, reorder=TRUE, ...)
```

Arguments

- `x` A numeric matrix-like object.
- `group, reorder, ...`
  See ?base::rowsum for a description of these arguments.

Value

See ?base::rowsum for the value returned by the default rowsum method.

The default colsum method returns t(rowsum(t(x),group,reorder=reorder, ...)).

See Also

- DelayedMatrix-utils in this package for the rowsum and colsum methods defined for DelayedMatrix objects.
- base::rowsum in the base package for the default rowsum method.
- dgCMatrix objects in the Matrix package.
Examples

```r
m0 <- rsparsematrix(1e5, 800, density=0.15)  # sparse representation
m <- as.matrix(m0)                          # dense representation

group <- sample(20, nrow(m), replace=TRUE)

## 'rowsum(m0)' is about 4x faster than 'rowsum(m)':
rs0 <- rowsum(m0, group)
rs <- rowsum(m, group)

stopifnot(identical(rs0, rs))
```

write_block (Write blocks of data to a RealizationSink)

Description

Use `write_block()` to write a block of array data to a RealizationSink derivative. `sinkApply()` is a convenience function for walking on a RealizationSink derivative, typically for the purpose of filling it with blocks of data.

Note that `write_block()` is typically used inside the callback function passed to `sinkApply()`.

Usage

```r
write_block(sink, viewport, block)
```

## Walk on a RealizationSink derivative:
`sinkApply(sink, FUN, ... , grid=NULL, verbose=NA)`

## Backend-agnostic RealizationSink constructor:
`AutoRealizationSink(dim, dimnames=NULL, type="double", as.sparse=FALSE)`

## Get/set the "automatic realization backend":
`getAutoRealizationBackend()`
`setAutoRealizationBackend(BACKEND=NULL)`
`supportedRealizationBackends()`

Arguments

- `sink`: A **writable** array-like object, typically a RealizationSink derivative. Some important notes:
  - `DelayedArray` objects are NEVER writable, even when they don’t carry delayed operations (e.g. `HDF5Array` objects from the `HDF5Array` package), and even when they don’t carry delayed operations **and** have all their data in memory (e.g. `RleArray` objects). In other words, there are NO exceptions.
• RealizationSink is a **virtual** class so sink will always be a RealizationSink **derivative**, that is, an object that belongs to a **concrete** subclass of the RealizationSink class (e.g. an HDF5RealizationSink object from the HDF5Array package).

• RealizationSink derivatives are considered array-like objects i.e. they have dimensions and possibly dimnames.

Although write_block() and sinkApply() will typically be used on a RealizationSink derivative, they can also be used on an ordinary array or other writable in-memory array-like objects like dgCMatrix objects from the Matrix package.

viewport
An ArrayViewport object compatible with sink, that is, such that refdim(viewport) is identical to dim(sink).

block
An ordinary (dense) array or SparseArraySeed object of the same dimensions as viewport.

FUN
The callback function to apply to each **viewport** of the grid used to walk on sink. sinkApply() will perform sink <-FUN(sink,viewport,...) on each viewport, so FUN must take at least two arguments, typically sink and viewport (but the exact names can differ).

The function is expected to return its 1st argument (sink) possibly modified (e.g. when FUN contains a call to write_block(), which is typically the case).

... Additional arguments passed to FUN.

grid
The grid used for the walk, that is, an ArrayGrid object that defines the viewports to walk on. It must be compatible with the geometry of sink. If not specified, an automatic grid is created by calling defaultSinkAutoGrid(sink), and used. See ?defaultSinkAutoGrid for more information.

verbose
Whether block processing progress should be displayed or not. If set to NA (the default), verbosity is controlled by DelayedArray:::getVerboseBlockProcessing(). Setting verbose to TRUE or FALSE overrides this.

dim
The dimensions (specified as an integer vector) of the RealizationSink derivative to create.

dimnames
The dimnames (specified as a list of character vectors or NULLs) of the RealizationSink derivative to create.

type
The type of the data that will be written to the RealizationSink derivative to create.

as.sparse
Whether the data should be written as sparse or not to the RealizationSink derivative to create. Not all realization backends support this.

BACKEND
NULL (the default), or a single string specifying the name of a realization backend e.g. "HDF5Array" or "RleArray" etc...

Details

*** The RealizationSink API ***

The DelayedArray package provides a simple API for writing blocks of array data to disk (or to memory): the "RealizationSink API". This API allows the developer to write code that is agnostic about the particular on-disk (or in-memory) format being used to store the data.

Here is how to use it:
1. Create a realization sink.
2. Write blocks of array data to the realization sink with one or several calls to write_block().
3. Close the realization sink with close().
4. Coerce the realization sink to DelayedArray.

A realization sink is formally represented by a RealizationSink derivative. Note that RealizationSink is a virtual class with various concrete subclasses like HDF5RealizationSink from the HDF5Array package, or RleRealizationSink. Each subclass implements the "RealizationSink API" for a specific realization backend.

To create a realization sink, use the specific constructor function. This function should be named as the class itself e.g. HDF5RealizationSink().

To create a realization sink in a backend-agnostic way, use AutoRealizationSink(). It will create a RealizationSink derivative for the current automatic realization backend (see below).

Once writing to the realization sink is completed, the RealizationSink derivative must be closed (with close(sink)), then coerced to DelayedArray (with as(sink,"DelayedArray")). What specific DelayedArray derivative this coercion will return depends on the specific class of the RealizationSink derivative. For example, if sink is an HDF5RealizationSink object from the HDF5Array package, then as(sink,"DelayedArray") will return an HDF5Array instance (the HDF5Array class is a DelayedArray subclass).

*** The automatic realization backend ***

The automatic realization backend is a user-controlled global setting that indicates what specific RealizationSink derivative AutoRealizationSink() should return. In the context of block processing of a DelayedArray object, this controls where/how realization happens e.g. as an ordinary array if not set (i.e. set to NULL), or as an HDF5Array object if set to "HDF5Array", or as an RleArray object if set to "RleArray", etc...

Use getAutoRealizationBackend() or setAutoRealizationBackend() to get or set the automatic realization backend.

Use supportedRealizationBackends() to get the list of realization backends that are currently supported.

*** Cross realization backend compatibility ***

Two important things to keep in mind for developers aiming at writing code that is compatible across realization backends:

- Realization backends don’t necessarily support concurrent writing.
  More precisely: Even though it is safe to assume that any DelayedArray object will support concurrent read_block() calls, it is not so safe to assume that any RealizationSink derivative will support concurrent calls to write_block(). For example, at the moment, HDF5RealizationSink objects do not support concurrent writing.
  This means that in order to remain compatible across realization backends, code that contains calls to write_block() should NOT be parallelized.
- Some realization backends are "linear write only", that is, they don’t support random write access, only linear write access.
  Such backends will provide a realization sink where the blocks of data must be written in linear order (i.e. by ascending rank). Furthermore, the geometry of the blocks must also be compatible with linear write access, that is, they must have a "first-dim-grows-first" shape.
Concretely this means that the grid used to walk on the realization sink must be created with something like:

```r
colAutoGrid(sink)
```
for a two-dimensional sink, or with something like:

```r
defaultSinkAutoGrid(sink)
```
for a sink with an arbitrary number of dimensions.

See ?defaultSinkAutoGrid for more information.

For obvious reasons, "linear write only" realization backends do not support concurrent writing.

**Value**

For `write_block()`, the modified array-like object `sink`.

For `sinkApply()`, its 1st argument (`sink`) possibly modified (e.g. when callback function `FUN` contains a call to `write_block()`, which is typically the case).

For `AutoRealizationSink()`, a RealizationSink derivative with the class associated with the current automatic realization backend.

For `getAutoRealizationBackend`, `NULL` (no backend set yet) or a single string specifying the name of the automatic realization backend currently in use.

For `supportedRealizationBackends`, a data frame with 1 row per supported realization backend.

**See Also**

- `defaultSinkAutoGrid` to create an automatic grid on a RealizationSink derivative.
- `ArrayGrid` for the formal representation of grids and viewports.
- `read_block`.
- `SparseArraySeed` objects.
- `blockApply` and family for convenient block processing of an array-like object.
- `HDF5RealizationSink` objects in the `HDF5Array` package.
- `HDF5-dump-management` in the `HDF5Array` package to control the location and physical properties of automatically created HDF5 datasets.
- `RleArray` objects.
- `DelayedArray` objects.
- `array` objects in base R.

**Examples**

```r
## ---------------------------------------------------------------------
## USING THE "RealizationSink API": EXAMPLE 1
## ---------------------------------------------------------------------

## -- STEP 1 --
## Create a realization sink. Note that instead of creating a
## realization sink by calling a backend-specific sink constructor

(e.g. HDF5Array::HDF5RealizationSink), we set the "automatic
realization backend" to "HDF5Array" and use backend-agnostic
constructor AutoRealizationSink():

```r
setAutoRealizationBackend("HDF5Array")
```

```r
sink <- AutoRealizationSink(c(35L, 50L, 8L))
dim(sink)
```

## -- STEP 2 --

Define the grid of viewports to walk on. Here we define a grid made
of very small viewports on 'sink'. Note that, for real-world use cases,
block processing will typically use grids made of much bigger
viewports, usually obtained with defaultSinkAutoGrid().
Also please note that this grid would not be compatible with "linear
write only" realization backends. See "Cross realization backend
compatibility" above in this man page for more information.

```r
sink_grid <- RegularArrayGrid(dim(sink), spacings=c(20, 20, 4))
```

## -- STEP 3 --

Walk on the grid, and, for each of viewport, write random data to it.

```r
for (bid in seq_along(sink_grid)) {
  viewport <- sink_grid[[bid]]
  block <- array(runif(length(viewport)), dim=dim(viewport))
  sink <- write_block(sink, viewport, block)
}
```

## -- An alternative to STEP 3 --

```r
FUN <- function(sink, viewport) {
  block <- array(runif(length(viewport)), dim=dim(viewport))
  write_block(sink, viewport, block)
}
```

```r
sink <- sinkApply(sink, FUN, grid=sink_grid, verbose=TRUE)
```

## -- STEP 4 --

Close the sink and turn it into a DelayedArray object:

```r
close(sink)
A <- as(sink, "DelayedArray")
```

```r
A
```

```r
setAutoRealizationBackend() # unset automatic realization backend
```

## USING THE "RealizationSink API": EXAMPLE 2

Say we have a 3D array and want to collapse its 3rd dimension by
summing the array elements that are stacked vertically, that is, we
want to compute the matrix M obtained by doing sum(A[i, j, ]) for all
valid i and j. This is very easy to do with an ordinary array:

```r
collapse_3rd_dim <- function(a) apply(a, MARGIN=1:2, sum)
```

## or, in a slightly more efficient way:

```r
collapse_3rd_dim <- function(a) {
```
## With a toy 3D array:

```r
da <- array(runif(8000), dim=c(25, 40, 8))
dim(collapse_3rd_dim(da))
```

stopifnot(identical(sum(da), sum(collapse_3rd_dim(da)))) # sanity check

## Now say that A is so big that even M wouldn't fit in memory. This is
## a situation where we'd want to compute M block by block:

```r
## -- STEP 1 --
## Create the 2D realization sink:
setAutoRealizationBackend("HDF5Array")
sink <- AutoRealizationSink(dim(da)[1:2])
dim(sink)
```

## -- STEP 2 --
## Define two grids: one for 'sink' and one for 'a'. Since we're going
## to walk on the two grids simultaneously, read a block from 'a' and
## write it to 'sink', we need to make sure that we define grids that
## are "aligned". More precisely the two grids must have the same number
## of viewports and the viewports in one must correspond to the viewports
## in the other one:

```r
sink_grid <- colAutoGrid(sink, ncol=10)
a_spacings <- c(dim(sink_grid[[1L]]), dim(a)[[3]])
a_grid <- RegularArrayGrid(dim(a), spacings=a_spacings)
dims(sink_grid) # dimensions of the individual viewports
dims(a_grid) # dimensions of the individual viewports
```

stopifnot(identical(length(sink_grid), length(a_grid)))
stopifnot(identical(dims(sink_grid), dims(a_grid)[, -3]))

## -- STEP 3 --
## Walk on the two grids simultaneously:
```
```r
for (bid in seq_along(sink_grid)) {
## Read block from 'a'.
a_viewport <- a_grid[[bid]]
block <- read_block(a, a_viewport)
## Collapse it.
block <- collapse_3rd_dim(block)
## Write the collapsed block to 'sink'.
sink_viewport <- sink_grid[[bid]]
sink <- write_block(sink, sink_viewport, block)
}
```

## -- An alternative to STEP 3 --
```
FUN <- function(sink, sink_viewport) {
## Read block from 'a'.
```

```r
m <- matrix(0, nrow=nrow(a), ncol=ncol(a))
for (z in seq_len(dim(a)[[3]]))
  m <- m + a[, , z]
```

```r
m
```
bid <- currentBlockId()
a_viewport <- a_grid[[bid]]
block <- read_block(a, a_viewport)
## Collapse it.
block <- collapse_3rd_dim(block)
## Write the collapsed block to 'sink'.
write_block(sink, sink_viewport, block)
}
sink <- sinkApply(sink, FUN, grid=sink_grid, verbose=TRUE)
## -- STEP 4 --
## Close the sink and turn it into a DelayedArray object:
close(sink)
M <- as(sink, "DelayedArray")
M
## Sanity check:
stopifnot(identical(collapse_3rd_dim(a), as.array(M)))
setAutoRealizationBackend() # unset automatic realization backend
## ---------------------------------------------------------------------
## USING THE "RealizationSink API": AN ADVANCED EXAMPLE
## ---------------------------------------------------------------------

## Say we have 2 matrices with the same number of columns. Each column
## represents a biological sample:
library(HDF5Array)
R <- as(matrix(runif(75000), ncol=1000), "HDF5Array") # 75 rows
G <- as(matrix(runif(250000), ncol=1000), "HDF5Array") # 250 rows

## Say we want to compute the matrix U obtained by applying the same
## binary functions FUN() to all samples i.e. U is defined as:
##
## U[, j] <- FUN(R[, j], G[, j]) for 1 <= j <= 1000
##
## Note that FUN() should return a vector of constant length, say 200,
## so U will be a 200x1000 matrix. A naive implementation would be:
##
## pFUN <- function(r, g) {
## stopifnot(ncol(r) == ncol(g)) # sanity check
## sapply(seq_len(ncol(r)), function(j) FUN(r[, j], g[, j]))
## }
##
## But because U is going to be too big to fit in memory, we can't
## just do pFUN(R, G). So we want to compute U block by block and
## write the blocks to disk as we go. The blocks will be made of full
## columns. Also since we need to walk on 2 matrices at the same time
## (R and G), we can't use blockApply() or blockReduce() so we'll use
## a "for" loop.
##
## Before we get to the "for" loop, we need 4 things:
## 1. Two grids of blocks, one on R and one on G. The blocks in the two grids must contain the same number of columns. We arbitrarily choose to use blocks of 150 columns:

R_grid <- colAutoGrid(R, ncol=150)
G_grid <- colAutoGrid(G, ncol=150)

## 2. The function pFUN(). It will take 2 blocks as input, 1 from R and 1 from G, apply FUN() to all the samples in the blocks, and return a matrix with one columns per sample:

pFUN <- function(r, g) {
  stopifnot(ncol(r) == ncol(g)) # sanity check
  ## Return a matrix with 200 rows with random values. Completely artificial sorry. A realistic example would actually need to apply the same binary function to r[,j] and g[,j] for 1 <= j <= ncol(r).
  matrix(runif(200 * ncol(r)), nrow=200)
}

## 3. A RealizationSink derivative where to write the matrices returned by pFUN() as we go:

setAutoRealizationBackend("HDF5Array")
U_sink <- AutoRealizationSink(c(200L, 1000L))

## 4. Finally, we create a grid on U_sink with viewports that contain the same number of columns as the corresponding blocks in R and G:

U_grid <- colAutoGrid(U_sink, ncol=150)

## Note that the three grids should have the same number of viewports:

stopifnot(length(U_grid) == length(R_grid))
stopifnot(length(U_grid) == length(G_grid))

## 5. Now we can proceed. We use a “for” loop to walk on R and G simultaneously, block by block, apply pFUN(), and write the output of pFUN() to U_sink:

for (bid in seq_along(U_grid)) {
  R_block <- read_block(R, R_grid[[bid]])
  G_block <- read_block(G, G_grid[[bid]])
  U_block <- pFUN(R_block, G_block)
  U_sink <- write_block(U_sink, U_grid[[bid]], U_block)
}

## An alternative to the “for” loop is to use sinkApply():

FUN <- function(U_sink, U_viewport) {
  bid <- currentBlockId()
  R_block <- read_block(R, R_grid[[bid]])
  G_block <- read_block(G, G_grid[[bid]])
  U_block <- pFUN(R_block, G_block)
  write_block(U_sink, U_viewport, U_block)
}

U_sink <- sinkApply(U_sink, FUN, grid=U_grid, verbose=TRUE)

close(U_sink)
U <- as(U_sink, "DelayedArray")
U

setAutoRealizationBackend() # unset automatic realization backend

### VERY BASIC (BUT ALSO VERY ARTIFICIAL) USAGE OF THE
### read_block()/write_block() COMBO
### -----------------------------------------------------------

#### On an ordinary matrix ####
m1 <- matrix(1:30, ncol=5)

## Define a viewport on 'm1':
block1_dim <- c(4, 3)
viewport1 <- ArrayViewport(dim(m1), IRanges(c(3, 2), width=block1_dim))

## Read/transform/write:
block1 <- read_block(m1, viewport1)
write_block(m1, viewport1, block1 + 1000L)

## Define another viewport on 'm1':
viewport1b <- ArrayViewport(dim(m1), IRanges(c(1, 3), width=block1_dim))

## Read/transform/write:
write_block(m1, viewport1b, block1 + 1000L)

## No-op:
m <- write_block(m1, viewport1, read_block(m1, viewport1))
stopifnot(identical(m1, m))

#### On a 3D array ####
a3 <- array(1:60, 5:3)

## Define a viewport on 'a3':
block3_dim <- c(2, 4, 1)
viewport3 <- ArrayViewport(dim(a3), IRanges(c(1, 1, 3), width=block3_dim))

## Read/transform/write:
block3 <- read_block(a3, viewport3)
write_block(a3, viewport3, block3 + 1000L)

## Define another viewport on 'a3':
viewport3b <- ArrayViewport(dim(a3), IRanges(c(3, 1, 3), width=block3_dim))

## Read/transform/write:
write_block(a3, viewport3b, block3 + 1000L)

## No-op:
a <- write_block(a3, viewport3, read_block(a3, viewport3))
stopifnot(identical(a3, a))

### LESS BASIC (BUT STILL VERY ARTIFICIAL) USAGE OF THE
## read_block()/write_block() COMBO

grid1 <- RegularArrayGrid(dim(m1), spacings=c(3L, 2L))
grid1
length(grid1)  # number of blocks defined by the grid
read_block(m1, grid1[[3L]])  # read 3rd block
read_block(m1, grid1[[1L, 3L]])

## Walk on the grid, column by column:
m1a <- m1
for (bid in seq_along(grid1)) {
  viewport <- grid1[[bid]]
  block <- read_block(m1a, viewport)
  block <- bid * 1000L + block
  m1a <- write_block(m1a, viewport, block)
}
m1a

## Walk on the grid, row by row:
m1b <- m1
for (i in seq_len(dim(grid1)[[1]])) {
  for (j in seq_len(dim(grid1)[[2]])) {
    viewport <- grid1[[i, j]]
    block <- read_block(m1b, viewport)
    block <- (i * 10L + j) * 1000L + block
    m1b <- write_block(m1b, viewport, block)
  }
}
m1b

## supportedRealizationBackends() AND FAMILY

getAutoRealizationBackend()  # no backend set yet

setAutoRealizationBackend("HDF5Array")
getAutoRealizationBackend()  # backend is set to "HDF5Array"
supportedRealizationBackends()
viewport <- grid[[bid]]
block <- 101 * bid + runif(length(viewport))
dim(block) <- dim(viewport)
sink <- write_block(sink, viewport, block)
}
close(sink)
A <- as(sink, "DelayedArray")
A

setAutoRealizationBackend()  # unset automatic realization backend
