Package ‘GPA’

May 29, 2024

Type Package
Version 1.16.0
Date 2020-02-24
Title GPA (Genetic analysis incorporating Pleiotropy and Annotation)
Author Dongjun Chung, Emma Kortemeier, Carter Allen
Maintainer Dongjun Chung <dongjun.chung@gmail.com>
Depends R (>= 4.0.0), methods, graphics, Rcpp
Imports parallel, ggplot2, ggrepel, plyr, vegan, DT, shiny, shinyBS, stats, utils, grDevices
Suggests gpaExample
LinkingTo Rcpp
Description
This package provides functions for fitting GPA, a statistical framework to prioritize GWAS results by integrating pleiotropy information and annotation data. In addition, it also includes ShinyGPA, an interactive visualization toolkit to investigate pleiotropic architecture.
License GPL (>= 2)

GPA-package GPA (Genetic analysis incorporating Pleiotropy and Annotation)

Description

This package provides functions for fitting GPA, a statistical approach to prioritizing GWAS results by integrating pleiotropy information and annotation data, along with ShinyGPA, a visualization toolkit to investigate the pleiotropic architecture using GWAS results.

This package contains a main class, GPA, which represents GPA model fit.
This package contains four main methods for the GPA framework (Chung et al., 2014), GPA, assoc, pTest, and aTest. GPA method fits the GPA model and assoc method implements association mapping. pTest and aTest methods implement hypothesis testing for pleiotropy and annotation enrichment, respectively.

This package contains two main methods for the ShinyGPA visualization toolkit (Kortemeier et al., 2017), fitAll and shinyGPA. fitAll function generates all the intermediate results needed to run shinyGPA. shinyGPA opens the ShinyGPA interface, which takes the results generated from fitAll as input.
GPA-package

```

# simulator function

```r
simulator <- function( risk.ind, nsnp=20000, alpha=0.6 ) {
m <- length(risk.ind)
p.sig <- rbeta( m, alpha, 1 )
pvec <- runif(nsnp)
pvec[ risk.ind ] <- p.sig
return(pvec)
}
```

# run simulation

```r
set.seed(12345)
nsnp <- 1000
alpha <- 0.4
pmat <- matrix( NA, nsnp, 5 )

pmat[,1] <- simulator( c(1:200), nsnp=nsnp, alpha=alpha )
pmat[,2] <- simulator( c(51:250), nsnp=nsnp, alpha=alpha )
pmat[,3] <- simulator( c(401:600), nsnp=nsnp, alpha=alpha )
pmat[,4] <- simulator( c(451:750), nsnp=nsnp, alpha=alpha )
pmat[,5] <- simulator( c(801:1000), nsnp=nsnp, alpha=alpha )
```
# Fit GPA for all possible pairs of GWAS datasets

out <- fitAll( pmat )

# Run the ShinyGPA app using the output from fitAll()

shinyGPA(out)

## End(Not run)

---

**assoc**  
*Association mapping*

---

**Description**

Association mapping.

**Usage**

assoc( object, ... )  
## S4 method for signature 'GPA'
assoc( object, FDR=0.05, fdrControl="global", pattern=NULL )

**Arguments**

- **object**: GPA model fit.
- **FDR**: FDR level.
- **fdrControl**: Method to control FDR. Possible values are "global" (global FDR control) and "local" (local FDR control). Default is "global".
- **pattern**: Pattern for association mapping. By default (i.e., pattern=NULL), assoc returns a binary matrix indicating association of SNPs for each phenotype. If a pattern is specified, a corresponding binary vector is provided. See the details about how users can specify the pattern.
- **...**: Other parameters to be passed through to generic assoc.

**Details**

assoc uses the direct posterior probability approach of Newton et al. (2004) to control global FDR in association mapping.

Users can specify the pattern using 1 and * in pattern argument, where 1 and * indicate phenotypes of interest and phenotypes that are not of interest, respectively. For example, when there are three phenotypes, pattern="111" means a SNP associated with all of three phenotypes, while pattern="11*" means a SNP associated with the first two phenotypes (i.e., association with the third phenotype is ignored (averaged out)).
Value

If `pattern=NULL`, returns a binary matrix indicating association of SNPs for each phenotype, where its rows and columns match those of input p-value matrix for function GPA. Otherwise, returns a binary vector indicating association of SNPs for the phenotype combination of interest.

Examples

```r
# simulator function
simulator <- function( risk.ind, nsnp=20000, alpha=0.6 ) {
  m <- length(risk.ind)
  p.sig <- rbeta( m, alpha, 1 )
  pvec <- runif(nsnp)
  pvec[ risk.ind ] <- p.sig
  return(pvec)
}

# run simulation
set.seed(12345)
nsnp <- 1000
alpha <- 0.3
pmat <- matrix( NA, nsnp, 5 )
pmat[,1] <- simulator( c(1:200), nsnp=nsnp, alpha=alpha )
pmat[,2] <- simulator( c(51:250), nsnp=nsnp, alpha=alpha )
pmat[,3] <- simulator( c(401:600), nsnp=nsnp, alpha=alpha )
pmat[,4] <- simulator( c(451:750), nsnp=nsnp, alpha=alpha )
pmat[,5] <- simulator( c(801:1000), nsnp=nsnp, alpha=alpha )
ann <- rbinom(n = nrow(pmat), size = 1, prob = 0.15)
ann <- as.matrix(ann,ncol = 1)
```
fit.GPA.wAnn <- GPA( pmat, ann, maxIter = 100 )
cov.GPA.wAnn <- cov( fit.GPA.wAnn )
assoc.GPA.wAnn <- assoc( fit.GPA.wAnn, FDR=0.05, fdrControl="global" )

---

**aTest**

*Hypothesis testing for annotation enrichment*

**Description**

    Hypothesis testing for annotation enrichment.

**Usage**

    aTest( fitWithoutAnn, fitWithAnn, vDigit=1000 )

**Arguments**

<table>
<thead>
<tr>
<th>fitWithoutAnn</th>
<th>GPA model fit without using annotation data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>fitWithAnn</td>
<td>GPA model fit with using annotation data.</td>
</tr>
<tr>
<td>vDigit</td>
<td>Number of digits for reporting parameter estimates and standard errors. For example, setting it to 1000 means printing out values up to three digits below zero.</td>
</tr>
</tbody>
</table>

**Details**

    aTest implements the hypothesis testing for annotation enrichment. It requires two GPA model fits, one fitted with using annotation data and one fitted without using annotation data, and evaluates annotation enrichment for risk-associated SNPs using the likelihood ratio test.

**Value**

Returns a list with components:

<table>
<thead>
<tr>
<th>q</th>
<th>q estimates.</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics</td>
<td>Statistics of the test for annotation enrichment.</td>
</tr>
<tr>
<td>pvalue</td>
<td>p-value of the test for annotation enrichment.</td>
</tr>
</tbody>
</table>

# GPA with annotation data

fit.GPA.wAnn <- GPA( pmat, ann, maxIter = 100 )

# hypothesis testing for annotation enrichment

test.annotation <- aTest( fit.GPA.noAnn, fit.GPA.wAnn )
**fitAll**

**Description**
Fit GPA model and the GPA model under H0 for all possible pairs of GWAS datasets.

**Usage**
```r
fitAll( pmat, 
   maxIter=2000, stopping="relative", epsStopLL=1e-10, 
   parallel=FALSE, nCore=8 )
```

**Arguments**
- `pmat`: p-value matrix from GWAS data, where row and column correspond to SNP and phenotype, respectively.
- `maxIter`: Maximum number of EM iteration. Default is 2000.
- `stopping`: Stopping rule for EM iteration. Possible values are "absolute" (based on absolute difference in log likelihood), "relative" (based on relative difference in log likelihood), or "aitken" (based on Aitken acceleration-based stopping rule). Default is "relative".
- `epsStopLL`: Threshold to stop the EM iteration. Default is 1e-100.
- `parallel`: Utilize multiple CPUs for parallel computing using "parallel" package? Possible values are TRUE (utilize multiple CPUs) or FALSE (do not utilize multiple CPUs). Default is FALSE (do not utilize multiple CPUs).
- `nCore`: Number of CPUs when parallel computing is utilized.

**Details**
`fitAll` function fits the GPA model and the GPA model under H0 for all possible pairs of GWAS datasets. Its output can be used as an input for the `shinyGPA` function.

**Value**
A list with 6 elements, including `pmat` (original GWAS p-value matrix), `combs` (a matrix of GWAS pair indices), `combList` (a matrix of GWAS pair indices), `pTestPval` (a matrix of pleiotropy test p-values), `fitGPA` (a list of the GPA fit for each pair), and `fitH0` (a list of the GPA fit under H0 for each pair).

  pvec <- runif(nsnp)
  pvec[ risk.ind ] <- p.sig
  return(pvec)
}

# run simulation
set.seed(12345)
nsnp <- 1000
alpha <- 0.4
pmat <- matrix( NA, nsnp, 5 )
pmat[,1] <- simulator( c(1:200), nsnp=nsnp, alpha=alpha )
pmat[,2] <- simulator( c(51:250), nsnp=nsnp, alpha=alpha )
pmat[,3] <- simulator( c(401:600), nsnp=nsnp, alpha=alpha )
pmat[,4] <- simulator( c(451:750), nsnp=nsnp, alpha=alpha )
pmat[,5] <- simulator( c(801:1000), nsnp=nsnp, alpha=alpha )

# Fit GPA for all possible pairs of GWAS datasets
out <- fitAll( pmat, maxIter = 100 )

---

**GPA**

**Fit GPA model**

Description

Fit GPA model.

Usage

GPA( gwasPval, annMat=NULL, pleiotropyH0=FALSE, empiricalNull=FALSE, maxIter=2000, stopping="relative", epsStopLL=1e-10, initBetaAlpha=0.1, initPi=0.1, initQ=0.75, lbPi=NA, lbBetaAlpha=0.001, lbQ=0.001, lbPval=1e-30, vDigit=1000, verbose=1 )
Arguments

- **gwasPval**: p-value matrix from GWAS data, where row and column correspond to SNP and phenotype, respectively.
- **annMat**: Binary matrix from annotation data, where row and column correspond to SNP and annotation, respectively.
- **pleiotropyH0**: Fit GPA under the null hypothesis of pleiotropy test? Possible values are TRUE (under the null hypothesis of pleiotropy test) or FALSE (usual assumption for GPA). Default is FALSE.
- **empiricalNull**: Empirically estimate null distribution for GPA? Possible values are TRUE (empirical null distribution) or FALSE (theoretical null distribution). Default is FALSE.
- **maxIter**: Maximum number of EM iteration. Default is 2000.
- **stopping**: Stopping rule for EM iteration. Possible values are "absolute" (based on absolute difference in log likelihood), "relative" (based on relative difference in log likelihood), or "aitken" (based on Aitken acceleration-based stopping rule). Default is "relative".
- **epsStopLL**: Threshold to stop the EM iteration. Default is 1e-100.
- **initBetaAlpha**: Initial value for alpha estimate. Default is 0.1.
- **initPi**: Initial value for pi estimate. Default is 0.1.
- **initQ**: Initial value for q estimate. Default is 0.75.
- **lbPi**: Lower bound for pi estimate. If lbPi=NA, lower bound is set to 1 / [number of SNPs]. Default is NA.
- **lbBetaAlpha**: Lower bound for alpha estimate. Default is 0.001.
- **lbQ**: Lower bound for q estimate. Default is 0.001.
- **lbPval**: Lower bound for GWAS p-value. Any GWAS p-values smaller than lbPval are set to lbPval. Default is 1e-30.
- **vDigit**: Number of digits for reporting parameter estimates. For example, setting it to 1000 means printing out values up to three digits below zero.
- **verbose**: Amount of progress report during the fitting procedure. Possible values are 0 (minimal output), 1, 2, or 3 (maximal output). Default is 1.

Details

**GPA** fits the GPA model. It requires to provide GWAS p-value to gwasPval, while users can also provide annotation data to annMat. It is assumed that number of rows of matrix provided to gwasPval equals to that provided to annMat.

**pTest** implements the hypothesis testing for pleiotropy. It requires two GPA model fits, one of interest and one under the null hypothesis, and they can be obtained by setting pleiotropyH0=FALSE and pleiotropyH0=TRUE, respectively.

**aTest** implements the hypothesis testing for annotation enrichment. It requires two GPA model fits, one fitted with using annotation data and one fitted without using annotation data, and they can be obtained by providing annotation data to annMat and not, respectively.
Value
Construct GPA class object.

cov.GPA.noAnn <- cov( fit.GPA.noAnn )

# GPA with annotation data
fit.GPA.wAnn <- GPA( pmat, ann, maxIter = 100 )
cov.GPA.wAnn <- cov( fit.GPA.wAnn )

# GPA under the null hypothesis of pleiotropy test
fit.GPA.pleiotropy.H0 <- GPA( pmat, NULL, pleiotropyH0=TRUE, maxIter = 100 )

---

**GPA-class**

**Class "GPA"**

**Description**

This class represents GPA model fit.

**Details**

When users use fdr method, users can specify the pattern using 1 and * in pattern argument, where 1 and * indicate phenotypes of interest and phenotypes that are not of interest, respectively. For example, when there are three phenotypes, pattern="111" means a SNP associated with all of three phenotypes, while pattern="11*" means a SNP associated with the first two phenotypes (i.e., association with the third phenotype is ignored (averaged out)).

**Objects from the Class**

Objects can be created by calls of the form new("GPA", ...).

**Slots**

- **fit**: Object of class "list", representing the fitted GPA model.
- **setting**: Object of class "list", representing the setting for GPA model fitting.
- **gwasPval**: Object of class "matrix", representing the p-value matrix from GWAS data.
- **annMat**: Object of class "matrix", representing the annotation matrix.

**Methods**

- **show** signature(object = "GPA"): provide brief summary of the object.
- **print** signature(x = "GPA"): provide the matrix of posterior probability that a SNP belongs to each combination of association status.
fdr signature(object = "GPA", pattern=NULL): provide local FDR. By default (i.e., pattern=NULL), it returns a matrix of local FDR that a SNP is not associated with each phenotype (i.e., marginal FDR), where the order of columns is same as that in input GWAS data. If a pattern is specified, a vector of corresponding local FDR is provided. See the details about how users can specify the pattern.

cov signature(object = "GPA", silent=FALSE, vDigitEst=1000, vDigitSE=1000 ): provide the covariance matrix for parameter estimates of GPA model. If silent=TRUE, it suppresses the summary output. vDigitEst and vDigitSE control number of digits for reporting parameter estimates and standard errors. For example, setting it to 1000 means printing out values up to three digits below zero.

estimates signature(object = "GPA"): extract parameter estimates from GPA model fit.

se signature(object = "GPA"): extract standard errors for parameter estimates from GPA model fit.

**GPA-internal**

**Internal GPA objects**

**Description**

Internal GPA objects.

**Details**

These are not to be called by the user.

---

**pTest**

**Hypothesis testing for pleiotropy**

**Description**

Hypothesis testing for pleiotropy.

**Usage**

`pTest( fit, fitH0, vDigit=1000 )`
Arguments

fit Fit of the GPA model of interest.
fitH0 GPA model fit under the null hypothesis of pleiotropy test.
vDigit Number of digits for reporting parameter estimates and standard errors. For example, setting it to 1000 means printing out values up to three digits below zero.

Details

pTest implements the hypothesis testing for pleiotropy. It requires two GPA model fits, one of interest and one under the null hypothesis (obtained by setting pleiotropyH0=TRUE when running GPA function), and evaluates genetical correlation among multiple phenotypes using the likelihood ratio test.

Value

Returns a list with components:

pi pi estimates.
piSE Standard errors for pi estimates.
statistics Statistics of the pleiotropy test.
pvalue p-value of the pleiotropy test.

### Description

Run ShinyGPA app.

### Usage

```r
shinyGPA(out=NULL)
```

### Arguments

- `out`: output of `fitAll` function.

### Details

shinyGPA runs the ShinyGPA app. It takes the output of the `fitAll` function, which fits the GPA model for all possible pairs of GWAS datasets, as input.
Value
Provides visualization to investigate pleiotropic architecture using GWAS results.
