Package ‘NormqPCR’

March 23, 2024

Version 1.48.0
Date 2018-07-09
Title Functions for normalisation of RT-qPCR data
Description Functions for the selection of optimal reference genes and the normalisation of real-time quantitative PCR data.
Author Matthias Kohl, James Perkins, Nor Izayu Abdul Rahman
Maintainer James Perkins <jimrperkins@gmail.com>
Depends R(>= 2.14.0), stats, RColorBrewer, Biobase, methods, ReadqPCR, qpcR
biocViews MicrotitrePlateAssay, GeneExpression, qPCR
License LGPL-3
LazyLoad yes
LazyData yes

NormqPCR-package

Functions for normalisation of RT-qPCR data.

Description

Functions for normalisation of real-time quantitative PCR data.

Details

Package: NormqPCR
Type: Package
Version: 1.7.1
Date: 2014-08-13
Depends: R(>= 2.14.0), stats, RColorBrewer, Biobase, methods, ReadqPCR, qpcR
Imports: ReadqPCR
biocViews: MicrotitrePlateAssay, GeneExpression, qPCR
License: LGPL-3
LazyLoad: yes
LazyData: yes

**Bladder**

*Bladder dataset of Andersen et al (2004)*

Description

This dataset was used in Andersen et al (2004) to demonstrate normalization of real-time quantitative RT-PCR data by geometric averaging of housekeeping genes.

Usage

```r
data(Bladder)
```

Format

A `qPCRBatch` object which contains an expression matrix with the expression of 14 genes measured in 28 samples. The sample information is saved in the `phenoData` slot with variables

- `Sample.no.` sample number.
- `Grade` Grade of bladder cancer.
The following information on the measured genes is saved in the variables Symbol and Gene.name of the featureData slot.

ATP5B  ATP synthase, H+ transporting, mitochondrial F1 complex, beta polypeptide.
HSPCB  Heat shock 90-kDa protein 1, beta.
S100A6  S100 calcium-binding protein A6 (calcylin).
FLOT2  Flotillin 2.
TEGT  Testis enhanced gene transcript (BAX inhibitor 1).
UBB  Ubiquitin B.
TPT1  Tumor protein, translationally controlled 1.
CFL1  Cofilin 1 (non-muscle).
ACTB  Actin, beta.
RPS13  Ribosomal protein S13.
RPS23  Ribosomal protein S23.
GAPD  Glyceraldehyde-3-phosphate dehydrogenase.
UBC  Ubiquitin C.
FLJ20030  Hypothetical protein FLJ20030.

For a detailed annotation see Table 1 in Anderson et al. (2004).

Details

The genes included in this data set were selected by screening 99 bladder sample expression profiles.

Source

The data set was obtained from http://www.mdl.dk/Publications_sup1.htm

head(exprs(Bladder))
pData(Bladder)
fData(Bladder)
Description

This dataset was used in Andersen et al (2004) to demonstrate normalization of real-time quantitative RT-PCR data by geometric averaging of housekeeping genes.

Usage

data(BladderRepro)

Format

A qPCRBatch object which contains an expression matrix with the expression of 8 genes measured in 26 samples. The sample information is saved in the phenoData slot with variables

Sample.no. sample number.
Grade Grade of bladder cancer.

The following information on the measured genes is saved in the variables Symbol and Gene.name of the featureData slot.

CD14 CD14 antigen.
FCN1 Ficolin (collagen/fibrinogen domain containing) 1.
CCNG2 Cyclin G2.
NPAS2 Neuronal PAS domain protein 2.
UBC Ubiquitin C.
CFL1 Cofilin 1 (non-muscle).
ACTB Actin, beta.
GAPD Glyceraldehyde-3-phosphate dehydrogenase.

For a detailed annotation see Table 1 and Supplementary table 1 in Anderson et al. (2004).

Details

This data set was used to check the reproducibility of the results obtained in Andersen et al (2004).

Source

The data set was obtained from http://www.mdl.dk/Publications_sup1.htm

```

Colon

Description

This dataset was used in Andersen et al (2004) to demonstrate normalization of real-time quantitative RT-PCR data by geometric averaging of housekeeping genes.

Usage

```r
data(Colon)
```

Format

A qPCRBatch object which contains an expression matrix with the expression of 13 genes measured in 40 samples. The sample information is saved in the phenoData slot with variables:

- `Sample.no`: sample number.
- `Classification`: Classification of colon cancer.

The following information on the measured genes is saved in the variables `Symbol` and `Gene.name` of the `featureData` slot.

- `UBC`: Ubiquitin C.
- `UBB`: Ubiquitin B.
- `SUI1`: Putative translation initiation factor.
- `FLJ20030`: Hypothetical protein FLJ20030.
- `CFL1`: Cofilin 1 (non-muscle).
- `ACTB`: Actin, beta.
- `CLTC`: Clathrin, heavy polypeptide (Hc).
- `RPS23`: Ribosomal protein S23.
- `GAPD`: Glyceraldehyde-3-phosphate dehydrogenase.
- `TPT1`: Tumor protein, translationally controlled 1.

For a detailed annotation see Table 1 in Anderson et al. (2004).
combineTechReps

Details

The genes included in this data set were selected by screening 161 colon sample expression profiles.

Source

The data set was obtained from http://www.mdl.dk/Publications_sup1.htm

combineTechReps

Combines Technical Replicates

Description

Takes expression set of qPCR values containing technical replicates and combines them.

Usage

combineTechReps(qPCRBatch, ...)

## S4 method for signature 'qPCRBatch'
combineTechReps(qPCRBatch, calc="arith")

Arguments

qPCRBatch Expression set containing qPCR data, read in by a ReadqPCR function and containing technical reps, denoted by _TechRep.n suffix.

... Extra arguments, detailed below

calc use median, arithmetic or geometric mean for combining the values

Details

Takes exprs of qPCR values containing technical replicates and combines them using a specified centrality measure.
**Value**

$q\text{PCRBatch}$ with same number of samples, but with less features, since all technical replicates are replaced with a single value of their means.

**Author(s)**

James Perkins <jimrperkins@gmail.com>

**References**

**Examples**

```r
path <- system.file("exData", package = "NormqPCR")
qPCR.example.techReps <- file.path(path, "qPCR.techReps.txt")
qPCRBatch.qPCR.techReps <- read.qPCR(qPCR.example.techReps)
rownames(exprs(qPCRBatch.qPCR.techReps))
combinedTechReps <- combineTechReps(qPCRBatch.qPCR.techReps)
rownames(exprs(combinedTechReps))
```

**combineTechRepsWithSD**  *Combines Technical Replicates*

**Description**

Takes expression set of qPCR values containing technical replicates and combines them. In addition the appropriate standard deviation (SD) is computed.

**Usage**

```r
combineTechRepsWithSD(qPCRBatch, ...)
```

```r
# S4 method for signature 'qPCRBatch'
combineTechRepsWithSD(qPCRBatch, calc="arith")
```

**Arguments**

- `qPCRBatch`  
  Expression set containing qPCR data, read in by a ReadqPCR function and containing technical reps, denoted by _TechRep.n suffix.

- `...`  
  Extra arguments, detailed below

- `calc`  
  use median, arithmetic or geometric mean for combining the values
ComputeNRQs

Details

Takes exprs of qPCR values containing technical replicates and combines them using a specified centrality measure.

The arithmetic mean (calc="arith") is combined with the classical standard deviation. In case of the geometric mean (calc="geom") the classical standard deviation of the log-values is exponentiated. The median (calc="median") is calculated in connection with the MAD.

Value

qPCRBatch with same number of samples, but with less features, since all technical replicates are replaced with a single value of their means. In addition the slot assayData includes a matrix with SD values which can be accessed via se.exprs.

Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

combineTechReps

Examples

```r
path <- system.file("exData", package = "NormqPCR")
qPCR.example.techReps <- file.path(path, "qPCR.techReps.txt")
qPCRBatch.qPCR.techReps <- read.qPCR(qPCR.example.techReps)
rownames(exprs(qPCRBatch.qPCR.techReps))
combinedTechReps <- combineTechRepsWithSD(qPCRBatch.qPCR.techReps)
rownames(exprs(combinedTechReps))
exprs(combinedTechReps)
se.exprs(combinedTechReps)
```
Usage

ComputeNRQs(qPCRBatch, ...)  
### S4 method for signature 'qPCRBatch'
ComputeNRQs(qPCRBatch, hkgs)

Arguments

qPCRBatch  
an object of class qPCRBatch.

hkgs  
Names of reference/housekeeping genes.

...  
other parameters to be passed to downstream methods.

Details

Allows the user to normalized relative quantities as defined in Hellemanns et al. (2007).

Value

Object of class "qPCRBatch".

qPCRBatch-class

Examples

```r
## Example data
path <- system.file("exData", package = "ReadqPCR")
qPCR.example <- file.path(path, "qPCR.example.txt")
Cq.data <- read.qPCR(qPCR.example)

## combine technichal replicates
Cq.data1 <- combineTechRepsWithSD(Cq.data)

## add efficiencies
Effs <- file.path(path, "Efficiencies.txt")
Cq.effs <- read.table(file = Effs, row.names = 1, header = TRUE)
```

CqValues

rownames(Cq.effs) <- featureNames(Cq.data1)
effs(Cq.data1) <- as.matrix(Cq.effs[, "efficiency", drop = FALSE])
se.effs(Cq.data1) <- as.matrix(Cq.effs[, "SD.efficiency", drop = FALSE])

##
res <- ComputeNRQs(Cq.data1, hkgs = c("gene_az", "gene_gx"))
## NRQs
exprs(res)
## SD of NRQs
se.exprs(res)

---

CqValues

*Compute Cq value and amplification efficiency*

**Description**

This function calculates Cq value and amplification efficiency for a `CyclesSet`. It is based on function `pcrbatch` of package `qpcR`.

**Usage**

```r
CqValues(object, ...)
## S4 method for signature 'CyclesSet'
CqValues(object, Effmethod = "expfit", group = NULL,
         model = l5, check = "uni2", checkPAR = parKOD(),
         remove = "none", exclude = NULL, type = "cpD2",
         labels = NULL, norm = FALSE, baseline = NULL,
         basefac = 1, smooth = NULL,
         smoothPAR = list(span = 0.1),
         factor = 1, opt = FALSE,
         optPAR = list(sig.level = 0.05, crit = "ftest"),
         plot = FALSE, verbose = FALSE, ...)
```

**Arguments**

- **object**: an object of class `CyclesSet`.
- **Effmethod**: a character vector defining the methods for computing amplification efficiency.
- **group**: a vector containing the grouping for possible replicates.
- **model**: the model to be used for all runs. Default model is l5.
- **check**: the method for kinetic outlier detection in `KOD`. Method "uni2" is set as default which is a test on sigmoidal structure.
- **checkPAR**: parameters to be supplied to the check method. See `parKOD`.
- **remove**: indicates which runs to be removed. Either none of them, those which failed to fit or from the outlier methods.
- **exclude**: indicates samples to be excluded from calculation, either "" for samples with missing column names or a regular expression defining columns (samples); see 'Details' and 'Examples' in `modlist`.

---

**Arguments**

- **object**: an object of class `CyclesSet`.
- **Effmethod**: a character vector defining the methods for computing amplification efficiency.
- **group**: a vector containing the grouping for possible replicates.
- **model**: the model to be used for all runs. Default model is l5.
- **check**: the method for kinetic outlier detection in `KOD`. Method "uni2" is set as default which is a test on sigmoidal structure.
- **checkPAR**: parameters to be supplied to the check method. See `parKOD`.
- **remove**: indicates which runs to be removed. Either none of them, those which failed to fit or from the outlier methods.
- **exclude**: indicates samples to be excluded from calculation, either "" for samples with missing column names or a regular expression defining columns (samples); see 'Details' and 'Examples' in `modlist`.
CqValues

- **type**: the point on the amplification curve which is used for efficiency estimation; see `efficiency`.
- **labels**: a vector containing labels which define replicate groups. See more details in `pcrbatch` and `ratiobatch`.
- **norm**: a logical value which determines whether the raw data should be normalized within \([0, 1]\) before model fitting or not.
- **baseline**: type of baseline subtraction. More details in `efficiency`.
- **basefac**: a factor when using averaged baseline cycles, such as 0.95.
- **smooth**: the curve smoothing method. See more details in `pcrbatch`.
- **smoothPAR**: parameters to be supplied to smoothing method in `smooth`.
- **factor**: a multiplication factor for the fluorescence response values.
- **opt**: a logical value which determines whether model selection should be applied to each model or not.
- **optPAR**: parameters to be supplied for model selection in `mselect`.
- **plot**: a logical value. If `TRUE`, the single runs are plotted from the internal `modlist` for diagnostics.
- **verbose**: a logical value. If `TRUE`, fitting and tagging results will be displayed in the console.
- **...**: other parameters to be passed to downstream methods.

**Details**

Allows the user to compute Cq value and amplification efficiency. In addition, all values generated during the computations are saved. This function has four choices of methods for computing amplification efficiency values which are the methods provided by package `qpcR`.

More details on technical replication and normalization is given in the vignette `NormqPCR`.

**Value**

Object of class "qPCRBatch".

se.effs(res3)

## 4) linear regression of efficiency
res4 <- CqValues(cycData1, Effmethod = "LRE")
res4
effs(res4)
se.effs(res4)
```

---

deltaCt

**Perform normalization with a given housekeeping gene**

Description

Normalise qPCR eset using a given housekeeping gene as control, then perform differential expression analysis using the delta delta Ct method

Usage

```r
deltaCt(qPCRBatch, ...)
```
## S4 method for signature 'qPCRBatch'

deltaCt(qPCRBatch, hkgs, combineHkgs=FALSE, calc="arith")
deltaCq(qPCRBatch, hkgs, combineHkgs=FALSE, calc="arith")

### Arguments

- **qPCRBatch**: qPCR-specific expression set, containing qPCR data.
- **hkgs**: String containing the name of the name of the housekeeping gene which will be used to normalise the rest of the genes.
- **combineHkgs**: Logical - if TRUE, then as long as more than one housekeeper given for argument hkgs, it will combine the housekeepers by finding the geometric mean. Housekeepers can be found using geNorm or NormFinder algorithms.
- **calc**: use arithmetic or geometric mean.

### Details

Takes expression set of qPCR values and normalises them using a housekeeping gene. Returns a qPCRBatch with exprs set of the same dimensions but with the given hkg value subtracted.

### Value

qPCRBatch with exprs set of the same dimensions but with the given hkg value subtracted.

### Author(s)

James Perkins <jimrperkins@gmail.com>

### References

### See Also

- selectHKs, deltaDeltaCq

### Examples

```r
path <- system.file("exData", package = "NormqPCR")
taqman.example <- file.path(path, "example.txt")
qPCRBatch.taqman <- read.taqman(taqman.example)
hkgs<-"Actb-Rn00667869_m1"
qPCRBatch.norm <- deltaCq(qPCRBatch = qPCRBatch.taqman, hkgs = hkgs, calc="arith")
head(exprs(qPCRBatch.norm))
```
**deltaDeltaCt**

Perform normalisation and differential expression with given housekeeping gene

---

**Description**

Normalise qPCRBatch RT-qPCR data using housekeeping genes as control, then perform differential expression analysis using the delta delta Cq method.

**Usage**

```r
deltaDeltaCt(qPCRBatch,...)
## S4 method for signature 'qPCRBatch'
deltaDeltaCt(qPCRBatch, maxNACase=0, maxNAControl=0, hkgs, contrastM, case, control, paired=TRUE, hkgCalc="arith", statCalc="arith")
deltaDeltaCq(qPCRBatch, maxNACase=0, maxNAControl=0, hkgs, contrastM, case, control, paired=TRUE, hkgCalc="arith", statCalc="arith")
```

**Arguments**

- `qPCRBatch`: qPCR-specific expression set, containing qPCR data.
- `...`: Extra arguments, detailed below
- `maxNACase`: Maximum number of NA values allowed before a detector’s reading is discarded for samples designated as case.
- `maxNAControl`: Maximum number of NA values allowed before a detector’s reading is discarded for samples designated as control.
- `hkgs`: String containing the name of the name of the housekeeping gene which will be used to normalise the rest of the genes.
- `contrastM`: A binary matrix which designates case and control samples.
- `case`: The name of the column in contrastM that corresponds to the case samples.
- `control`: The name of the column in contrastM that corresponds to the control samples.
- `paired`: Logical - if TRUE the detectors and housekeepers in the same sample will be paired for calculating standard deviation, effectively meaning we will be calculating standard deviation of the differences. If FALSE, there will be no pairing, and standard deviation will be pooled between the detector and housekeepers.
- `hkgCalc`: String - either "arith" or "geom", details how the different housekeeper genes should be combined - either by using the arithmetic or geometric mean.
- `statCalc`: String - either "arith" or "geom", details how genes should be combined - either by using the arithmetic or geometric mean.

**Details**

Takes expression set of qPCR values and normalises them using different housekeeping genes. Returns separate sets of values for each housekeeping gene given.
Value

matrix with columns containing the detector ids, 2^\(\Delta\)Cq values for the sample of interest and the calibrator sample, alongside their respective standard deviations, the 2^\(\Delta\)\(\Delta\)Cq values and the minimum and maximum values (ie the values that are 1 sd away)

head(ddCq.taqman)
```

geNorm

Data set of Vandesompele et al (2002)

Description

This data set was used in Vandesompele et al (2002) to demonstrate normalization of real-time quantitative RT-PCR data by geometric averaging of housekeeping genes.
Usage
data(geNorm)

Format
A qPCRBatch object which contains an expression matrix with 85 observations on the following 10 variables which stand for expression data of ten potential reference/housekeeping genes

ACTB  actin, beta
B2M  beta-2-microglobulin
GAPD  glyceraldehyde-3-phosphate dehydrogenase
HMBS  hydroxymethylbilane synthase
HPRT1  hypoxanthine phosphoribosyltransferase 1
RPL13A  ribosomal protein L13a
SDHA  succinate dehydrogenase complex subunit A
TBP  TATA box binding protein
UBC  ubiquitin C
YWHAZ  tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein, zeta polypeptide

Details
The row names of this data set indicate the various human tissues which were investigated.

BM  9 normal bone-marrow samples
POOL  9 normal human tissues from pooled organs (heart, brain, fetal brain, lung, trachea, kidney, mammary gland, small intestine and uterus)
FIB  20 short-term cultured normal fibroblast samples from different individuals
LEU  13 normal leukocyte samples
NB  34 neuroblastoma cell lines (independently prepared in different labs from different patients)

Source
The data set was obtained from http://genomebiology.com/content/supplementary/gb-2002-3-7-research0034-s1.txt

sampleNames(geNorm.qPCRBatch)
```

---

### geomMean

**Geometric Mean**

**Description**

Computation of the geometric mean.

**Usage**

```r
geomMean(x, na.rm = TRUE)
```

**Arguments**

- `x`: numeric vector of non-negative Reals
- `na.rm`: a logical value indicating whether NA values should be stripped before the computation proceeds.

**Details**

The computation of the geometric mean is done via `prod(x)^(1/length(x))`.

**Value**

geometric mean

**Note**

A first version of this function appeared in package SLqPCR.

**Author(s)**

Matthias Kohl <Matthias.Kohl@stamats.de>

**References**

**Examples**

```r
x <- rlnorm(100)
geomMean(x)
```
makeAllNAs

Make all Cq values NA

Description

Make all Cq values for a given detector NA when the number of NAs for that detector is above a given threshold.

Usage

makeAllNAs(qPCRBatch, ...)

# S4 method for signature 'qPCRBatch'
makeAllNAs(qPCRBatch, contrastM, sampleMaxM)

Arguments

qPCRBatch Expression set containing qPCR data.
...
contrastM Contrast Matrix like that used in limma. Columns represent the different sample types, rows are the different samples, with a 1 or 0 in the matrix indicating which sample types the different samples belong to.
sampleMaxM Sample Max Matrix. Columns represent the different sample types. There is one value per column, which represents the max number of NAs allowed for that sample type.

Details

Make all NAs when number of NAs above a given threshold.

Value

qPCRBatch object with a new exprs slot, everything else equal.

Author(s)

James Perkins <jimrperkins@gmail.com>

Examples

```r
# read in the data
path <- system.file("exData", package = "NormqPCR")
taqman.example <- file.path(path, "example.txt")
qPCRBatch.taqman <- read.taqman(taqman.example)
exprs(qPCRBatch.taqman)["Ccl20_Rn00570287_m1",] # values before

# make contrastM
a <- c(0,0,1,1,0,0,1,1) # one for each sample type, with 1 representing
b <- c(1,1,0,0,1,1,0,0) # position of sample type in the samplenames vector
contM <- cbind(a,b)
colnames(contM) <- c("case","control") # then give the names of each sample type
rownames(contM) <- sampleNames(qPCRBatch.taqman) # and the rows of the matrix
contM

# make sampleMaxM
sMaxM <- t(as.matrix(c(3,3))) # now make the sample max matrix
colnames(sMaxM) <- c("case","control") # make sure these line up with samples
sMaxM

# function
qPCRBatch.taqman.replaced <- makeAllNAs(qPCRBatch.taqman, contM, sMaxM)
exprs(qPCRBatch.taqman.replaced)["Ccl20_Rn00570287_m1",]
```

makeAllNewVal (makeAllNewVal)

**Make all Cq values NA**

Description

Make all Cq values for a given detector NA when the number of NAs for that detector is above a given threshold

Usage

```r
makeAllNewVal(qPCRBatch, 

## S4 method for signature 'qPCRBatch'
makeAllNewVal(qPCRBatch, contrastM, sampleMaxM, newVal)
```

Arguments

- **qPCRBatch**: Expression set containing qPCR data.
- **contrastM**: Contrast Matrix like that used in limma. Columns represent the different samples types, rows are the different samples, with a 1 or 0 in the matrix indicating which sample types the different samples belong to.
- **sampleMaxM**: Sample max matrix.
- **newVal**: Value to replace NA values with.
Sample Max Matrix. Columns represent the different sample types. There is one value per column, which represents the max number of NAs allowed for that sample type.

New value to give the values in the group where the NAs are above the threshold.

Details

Make all a given value when number of NAs above a given threshold, with different thresholds for the different sample classes, using sMaxM and contM to provide this information, as detailed below.

Value

qPCRBatch object with a new exprs slot, everything else equal

qPCRBatch.taqlman.replaced <- makeAllNewVal(qPCRBatch.taqlman, contM, sMaxM)
exprs(qPCRBatch.taqlman.replaced)["Ccl20.Rn00570287_m1",]
replaceAboveCutOff

Replace Cq values with new value

Description

Replace Cq values above a given threshold with a new value

Usage

replaceAboveCutOff(qPCRBatch, ...)  
## S4 method for signature 'qPCRBatch'
replaceAboveCutOff(qPCRBatch, newVal=NA, cutOff=38)

Arguments

  qPCRBatch  Expression set containing qPCR data.
  ...        Extra arguments, detailed below
  newVal     The new value with which to replace the values above the cutoff
  cutOff     the minimal threshold above which the values will be replaced

Details

Replaces values in the exprs slot of the qPCRBatch object that are above a threshold value with a new number

Value

qPCRBatch object with a new exprs slot

Author(s)

James Perkins <jimrperkins@gmail.com>

taqman.example <- file.path(path, "example.txt")
qPCRBatch.taqman <- read.taqman(taqman.example)
exprs(qPCRBatch.taqman)["Ccl20.Rn00570287_m1",]
qPCRBatch.taqman.replaced <- replaceAboveCutOff(qPCRBatch.taqman, newVal = NA, cutOff = 35)
exprs(qPCRBatch.taqman.replaced)["Ccl20.Rn00570287_m1",]
replaceNAs

Replace NAs with a given value

Description
Replace NAs with a given value

Usage
replaceNAs(qPCRBatch, ...)

## S4 method for signature 'qPCRBatch'
replaceNAs(qPCRBatch, newNA)

Arguments
qPCRBatch Expression set containing qPCR data.
...
Extra arguments, detailed below
newNA The new value to replace the NAs with

Details
Replaces NA values in the exprs slot of the qPCRBatch object with a given number

Value
qPCRBatch object with a new exprs slot

selectHKs

**Selection of reference/housekeeping genes**

**Description**

This function can be used to determine a set of reference/housekeeping (HK) genes for gene expression experiments.

**Usage**

```r
selectHKs(qPCRBatch, ...) 
## S4 method for signature 'matrix'
selectHKs(qPCRBatch, group, method = "geNorm", minNrHKs = 2, log = TRUE, Symbols, trace = TRUE, na.rm = TRUE)

## S4 method for signature 'qPCRBatch'
selectHKs(qPCRBatch, group, method = "geNorm", minNrHKs = 2, log = TRUE, Symbols, trace = TRUE, na.rm = TRUE)
```

**Arguments**

- `qPCRBatch`: matrix or qPCRBatch, containing the data (expression matrix) in the exprs slot
- `...`: Extra arguments, detailed below
- `group`: optional factor not used by all methods, hence may be missing
- `method`: method to compute most stable genes
- `minNrHKs`: minimum number of HK genes that should be considered
- `log`: logical: is data on log-scale
- `Symbols`: gene symbols
- `trace`: logical, print additional information
- `na.rm`: a logical value indicating whether NA values should be stripped before the computation proceeds.

**Details**

This function can be used to determine a set of reference/housekeeping (HK) genes for gene expression experiments. The default method "geNorm" was proposed by Vandesompele et al. (2002).

Currently, the geNorm method by Vandesompele et al. (2002) and the NormFinder method of Andersen et al. (2004) are implemented.

Vandesompele et al. (2002) propose a cut-off value of 0.15 for the pairwise variation. Below this value the inclusion of an additional housekeeping gene is not required.
Value
If method = "geNorm" a list with the following components is returned

- **ranking**: ranking of genes from best to worst where the two most stable genes cannot be ranked
- **variation**: pairwise variation during stepwise selection
- **meanM**: average expression stability M

If method = "NormFinder" a list with the following components is returned

- **ranking**: ranking of genes from best to worst where the two most stable genes cannot be ranked
- **rho**: stability measure rho of Andersen et al. (2004)

Author(s)
Matthias Kohl <Matthias.Kohl@stamats.de>

References

Examples
```r
data(geNorm)
tissue <- as.factor(c(rep("BM", 9), rep("FIB", 20), rep("LEU", 13),
rep("NB", 34), rep("POOL", 9)))
res.BM <- selectHKs(geNorm.qPCRBatch[, tissue == "BM"], method = "geNorm",
  Symbols = featureNames(geNorm.qPCRBatch), minNrHK = 2,
  log = FALSE)
```
**stabMeasureM**

Gene expression stability value $M$

### Description

Computation of the gene expression stability value $M$ for real-time quantitativ RT-PCR data. For more details we refer to Vandesompele et al. (2002).

### Usage

```r
stabMeasureM(x, log = TRUE, na.rm = TRUE)
```

### Arguments

- `x`: matrix or data.frame containing real-time quantitative RT-PCR data
- `log`: logical: is data on log-scale
- `na.rm`: a logical value indicating whether NA values should be stripped before the computation proceeds.

### Details

The gene expression stability value $M$ is defined as the average pairwise normalization factor; i.e., one needs to specify data from at least two genes. For more details see Vandesompele et al. (2002). Note this dispatches on a transposed expression matrix, not a qPCRBatch object since it is only called from within the selectHKs method.

### Value

numeric vector with gene expression stability values

### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

selectHKs
**Examples**

```r
data(geNorm)
tissue <- as.factor(c(rep("BM", 9), rep("FIB", 20), rep("LEU", 13),
                    rep("NB", 34), rep("POOL", 9)))
res.BM <- selectHKs(geNorm.qPCRBatch[, tissue == "BM"], method = "geNorm",
                    Symbols = featureNames(geNorm.qPCRBatch), minNrHK = 2, log = FALSE)
```

---

**stabMeasureRho**

*Gene expression stability value rho*

**Description**

Computation of the gene expression stability value rho for real-time quantitative RT-PCR data. For more details we refer to Andersen et al. (2004).

**Usage**

```r
stabMeasureRho(x, ...)
```

```r
# S4 method for signature 'x'
stabMeasureRho(x, group, log = TRUE, na.rm = TRUE, returnAll = FALSE)
```

**Arguments**

- `x`: matrix containing real-time quantitative RT-PCR data, or qPCRBatch object
- `...`: Extra arguments, detailed below
- `group`: grouping factor, either a factor vector or a phenoData column called "Group"
- `log`: logical: is data on log-scale
- `na.rm`: a logical value indicating whether NA values should be stripped before the computation proceeds.
- `returnAll`: logical, return additional information.

**Details**

The gene expression stability value rho is computed. For more details see Andersen et al. (2004).

**Value**

numeric vector with gene expression stability values

If `returnAll` == `TRUE` a list with the following components is returned:

- `d`: used by `selectHKs`
- `v`: used by `selectHKs`
