Package ‘ROSeq’

March 28, 2024

Type Package

Title Modeling expression ranks for noise-tolerant differential expression analysis of scRNA-Seq data

Version 1.14.0

Description ROSeq - A rank based approach to modeling gene expression with filtered and normalized read count matrix. ROSeq takes filtered and normalized read matrix and cell-annotation/condition as input and determines the differentially expressed genes between the contrasting groups of single cells. One of the input parameters is the number of cores to be used.

computeDEG

Computes differential expression for the gene in question, by comparing the optimal parameters for sub-populations one and two

Usage

computeDEG(results_1, results_2)
findParams

Arguments

results_1 A vector corresponding to sub-population one and containing 5 values (a, b, A, number of bins, R2)
results_2 A vector corresponding to sub-population two and containing 5 values (a, b, A, number of bins, R2)

Value

T The Wald test statistic for testing the null hypothesis

See Also

getI, findParams

Description

Takes in as input the read count data corresponding to one sub-population and the typical gene statistics. Then it splits the entire range into equally sized bins of size $k \times \sigma$, where $k$ is a scalar with a default value of 0.05, and $\sigma$ is the standard deviation of the pulled expression estimates across the cell-groups. Each of these bins corresponds to a rank. Therefore, for each group, cell frequency for each bin maps to a rank. These frequencies are normalized group-wise by dividing by the total cell count within a concerned group.

Usage

findParams(ds, geneStats)

Arguments

ds The (normalized and filtered) read count data corresponding to a sub-population
geneStats A vector containing 7 values corresponding to the gene data (maximum, minimum, mean, standard deviation, upper multiple of the standard deviation, lower multiple of standard deviation and log_2(fold change))

Value

results A vector containing 5 values (a, b, A, number of bins, R2)
getd  

Finds the double derivative of $A$

**Description**

Finds the double derivative of $A$ with respect to $a, (a, b), b, (a, b)$ in respective templates from right to left. This first derivative is evaluated at the optimal $(\hat{a}, \hat{b})$. $u_1, v$ and $u_2$ constitute the equations required for evaluating the first and second order derivatives of $A$ with respect to parameters $a$ and $b$.

**Usage**

getd($u_1$, $v$, $du_1da$, $dvda$)

**Arguments**

- $u_1$
- $v$
- $du_1da$ First derivative of $u_1$ with respect to parameter $a$
- $dvda$ First derivative of $v$ with respect to parameter $a$

**Value**

$d_2logAda2$

---

getDataStatistics  

Evaluates statistics of the read counts corresponding to the gene

**Description**

Takes in the complete read count vector corresponding to the gene ($sp$) and also the data corresponding to the two sub-populations ($sp1$ and $sp2$).

**Usage**

gedataStatistics($sp$, $spOne$, $spTwo$)

**Arguments**

- $sp$ The complete (normalized and filtered) read count data corresponding to the gene in question
- $spOne$ The (normalized and filtered) read count data corresponding to the first sub-population
- $spTwo$ The (normalized and filtered) read count data corresponding to the second sub-population
Value

geneStats A vector containing 6 values corresponding to the gene data (maximum, minimum, mean, standard deviation, upper multiple of standard deviation and lower multiple of standard deviation)

table

getdulda

Finds the first derivative of u1 with respect to a. This first derivative is evaluated at the optimal (a_hat, b_hat).

Description

u1, v and u2 constitute the equations required for evaluating the first and second order derivatives of A with respect to parameters a and b

Usage

goingdulda(coefficients, r)

Arguments

coefficients the optimal values of a and b
    r the rank vector

Value

du1da

getdu1db

Finds the first derivative of u1 with respect to b. This first derivative is evaluated at the optimal (a_hat, b_hat).

Description

u1, v and u2 constitute the equations required for evaluating the first and second order derivatives of A with respect to parameters a and b

Usage

goingdu1db(coefficients, r)

Arguments

coefficients the optimal values of a and b
    r the rank vector

Value

du1db
getdu2da

Finds the first derivative of $u_2$ with respect to $a$. This first derivative is evaluated at the optimal $(a_{\hat{}}_{}$, $b_{\hat{}}_{}$).

Description

$u_1$, $v$ and $u_2$ constitute the equations required for evaluating the first and second order derivatives of $A$ with respect to parameters $a$ and $b$.

Usage

getdu2da(coefficients, r)

Arguments

- coefficients: the optimal values of $a$ and $b$
- r: the rank vector

Value

du2da

getdu2db

Finds the first derivative of $u_2$ with respect to $b$. This first derivative is evaluated at the optimal $(a_{\hat{}}_{}$, $b_{\hat{}}_{}$).

Description

$u_1$, $v$ and $u_2$ constitute the equations required for evaluating the first and second order derivatives of $A$ with respect to parameters $a$ and $b$.

Usage

getdu2db(coefficients, r)

Arguments

- coefficients: the optimal values of $a$ and $b$
- r: the rank vector

Value

du2db
**getdvda**

Finds the first derivative of v with respect to a. This first derivative is evaluated at the optimal ($a_{hat}, b_{hat}$).

**Description**

$u_1$, v and $u_2$ constitute the equations required for evaluating the first and second order derivatives of A with respect to parameters a and b.

**Usage**

```plaintext
getdvda(coefficients, r)
```

**Arguments**

- **coefficients**
  
  the optimal values of a and b

- **r**
  
  the rank vector

**Value**

dvda

---

**getdvdb**

Finds the first derivative of v with respect to b. This first derivative is evaluated at the optimal ($a_{hat}, b_{hat}$).

**Description**

$u_1$, v and $u_2$ constitute the equations required for evaluating the first and second order derivatives of A with respect to parameters a and b.

**Usage**

```plaintext
getdvdb(coefficients, r)
```

**Arguments**

- **coefficients**
  
  the optimal values of a and b

- **r**
  
  the rank vector

**Value**

dvdb
getI  

**Fisher Information Matrix**

*Description*

The Fisher Information Matrix and its derivatives are essential to evaluate the minima of log likelihood.

*Usage*

```
getI(results)
```

*Arguments*

- **results**: A vector containing 5 values (a, b, A, number of bins, R2)

*Value*

- **I**: The Fisher Information Matrix

---

getu1  

**Computes u1**

*Description*

u1, v and u2 constitute the equations required for evaluating the first and second order derivatives of A with respect to parameters a and b.

*Usage*

```
getu1(coefficients, r)
```

*Arguments*

- **coefficients**: the optimal values of a and b
- **r**: the rank vector

*Value*

- **u1**
getu2

Description

\( u_1, v \) and \( u_2 \) constitute the equations required for evaluating the first and second order derivatives of \( A \) with respect to parameters \( a \) and \( b \).

Usage

\texttt{getu2(coefficients, r)}

Arguments

- \texttt{coefficients} the optimal values of \( a \) and \( b \)
- \texttt{r} the rank vector

Value

\( u_2 \)

getv

Description

\( u_1, v \) and \( u_2 \) constitute the equations required for evaluating the first and second order derivatives of \( A \) with respect to parameters \( a \) and \( b \).

Usage

\texttt{getv(coefficients, r)}

Arguments

- \texttt{coefficients} the optimal values of \( a \) and \( b \)
- \texttt{r} the rank vector

Value

\( v \)
**initiateAnalysis**  
*Computes differential analysis for a given gene*

**Description**
Takes in the row index which corresponds to a gene and evaluates for differential expression across two cell types.

**Usage**
```r
initiateAnalysis(gene, scdata, scgroups, classOne, classTwo)
```

**Arguments**
- **gene**: The row index of the normalised and filtered, read count matrix
- **scdata**: The normalised and filtered, read count matrix
- **scgroups**: The location of the two sub-populations
- **classOne**: The location of the first sub-population, for example, sample names as given as columns names
- **classTwo**: The location of the second sub-population, for example, sample names as given as columns names

**Value**
- **combinedResults**: A vector containing 12 values (gr1: a, g1: b, gr1: A, gr1: number of bins, gr1: R2, gr2: a, gr2: b, gr2: A, gr2: number of bins, gr2: R2, T, p)

**L_Tung_single**  
*Single cell samples for DE genes analysis*

**Description**
Three replicates from three human induced pluripotent stem cell (iPSC) lines were considered. 96 single cells were considered in each of the three replicates corresponding to one of the three individuals (these shall be referred to by their labels NA19098, NA19101 and NA19239).

**Usage**
```r
data("L_Tung_single")
```

**Format**
The format is: list of cells corresponding NA19098 versus NA19101 and groups labels.
**minimizeNLL**

Details

filtered and normalized data

Source

References

Examples

data(L_Tung_single)
## summary(R0Seq::L_Tung_single)

---

**minimizeNLL**  
Minimizes the Negative Log-Likelihood by iterating across values of parameters a and b

Description

Takes in as input a vector of values (coefficients), the number of bins and the normalized probability distribution of ranks

Usage

minimizeNLL(coefficients, r, readCount)

Arguments

- **coefficients**: A vector containing two values for a and b
- **r**: The number of bins
- **readCount**: A vector of (normalized) frequency of read counts that fall within each bin

Value

NLL Negative-Log Likelihood for the input coefficients

findParams
ROSeq

Modeling expression ranks for noise-tolerant differential expression analysis of scRNA-Seq data

Description

Takes in the complete filtered and normalized read count matrix, the location of the two sub-populations and the number of cores to be used

Usage

ROSeq(countData, condition, numCores = 1)

Arguments

countData The normalised and filtered, read count matrix, with row names as genes name/ID and column names as sample id/name
condition Labels for the two sub-populations
numCores The number of cores to be used

Value

pValues and FDR adjusted p significance values

Examples

countData<-list()
countData$count<ROSeq::L_Tung_single$NA19098_NA19101_count
countData$group<ROSeq::L_Tung_single$NA19098_NA19101_group
head(countData$count)
gene_names<rownames(countData$count)
countData$count<apply(countData$count,2,function(x) as.numeric(x))
rownames(countData$count)<gene_names
countData$count<countData$count[,colSums(countData$count> 0) > 2000]
g_keep <- apply(countData$count,1,function(x) sum(x>2)>=3)
countData$count<countData$count[g_keep,]
countData$count<-limma::voom(ROSeq::TMMnormalization(countData$count))
output<-ROSeq(countData=countData$count$E, condition = countData$group)
output
TMMnormalization

Description
Trimmed Means of M values (TMM) normalization (on the basis of edgeR package)

Usage
TMMnormalization(countTable)

Arguments
- countTable: The filtered, read count matrix, with row names as genes name/ID and column names as sample id/name

Value
countTableTMM

Examples
```r
countData<-list()
countData$count<-ROSeq::L_Tung_single$NA19098_NA19101_count
countData$group<-ROSeq::L_Tung_single$NA19098_NA19101_group
head(countData$count)
gene_names<-rownames(countData$count)
countData$count<-apply(countData$count,2,function(x) as.numeric(x))
rownames(countData$count)<-gene_names
countData$count<-countData$count[,colSums(countData$count> 0) > 2000]
g_keep <- apply(countData$count,1,function(x) sum(x>2)>=3)
countData$count<-countData$count[g_keep,]
countTableTMM<-ROSeq::TMMnormalization(countData$count)
countTableTMM
