Package ‘dearseq’

May 17, 2024

Type Package

Title Differential Expression Analysis for RNA-seq data through a robust variance component test

Version 1.16.0

Date 2023-06-16

Depends R (>= 3.6.0)

Imports CompQuadForm, dplyr, ggplot2, KernSmooth, magrittr, matrixStats, methods, patchwork, parallel, pbapply, reshape2, rlang, scattermore, stats, statmod, survey, tibble, viridisLite

Suggests Biobase, BiocManager, BiocSet, edgeR, DESeq2, GEOquery, GSA, knitr, limma, readxl, rmarkdown, S4Vectors, SummarizedExperiment, testthat, covr

License GPL-2 | file LICENSE

Description

Details

Analysis of RNA-seq data with variance component score test accounting for data heteroscedasticity through precision weights. Performs gene-wise analysis as well as gene set analysis, including for complex experimental designs such as longitudinal data.

baduel_5gs  Small portion of RNA-seq data from plant physiology study.

Description

A subsample of the RNA-seq data from Baduel et al. studying Arabidopsis Arenosa physiology.

Usage

data(baduel_5gs)

Format

3 objects

- design: a design matrix for the 48 measured samples, containing the following variables:
  - SampleName corresponding column names from expr_norm_corr
  - Intercept an intercept variable
  - Population a factor identifying the plant population
  - Age_weeks numeric age of the plant at sampling time (in weeks)
  - Replicate a purely technical variable as replicates are not from the same individual over weeks. Should not be used in analysis.
  - Vernalized a logical variable indicating whether the plant had undergone vernalization (exposition to cold and short day photoperiods)
  - Vernalized a binary variable indicating whether the plant belonged to the KA population
  - AgeWeeks_Population interaction variable between the AgeWeeks and Population variables
  - AgeWeeks_Vernalized interaction variable between the AgeWeeks and Vernalized variables
  - Vernalized_Population interaction variable between the Vernalized and Population variables
  - AgeWeeks_Vernalized_Population interaction variable between the AgeWeeks, Vernalized and Population variables
- baduel_gmt: a gmt object containing 5 gene sets of interest (see GSA.read.gmt), which is simply a list with the 3 following components:
  - genesets: a list of n gene identifiers vectors composing each gene set (each gene set is represented as the vector of the gene identifiers composing it)
  - geneset.names: a vector of length n containing the gene set names (i.e. gene sets identifiers)
baduel_5gs

- geneset.descriptions: a vector of length \( n \) containing gene set descriptions (e.g. textual information on their biological function)

- expr_norm_corr: a numeric matrix containing the normalized batch corrected expression for the 2454 genes included in either of the 5 gene sets of interests

```r
if(interactive()){
  data('baduel_5gs')

  set.seed(54321)
  KAvsTBG <- dgsa_seq(exprmat=log2(expr_norm_corr+1),
                     covariates=apply(as.matrix(design[, c('Intercept', 'Vernalized', 'AgeWeeks', 'Vernalized_Population', 'AgeWeeks_Population')]), 2, as.numeric),
                     variables2test = as.matrix(design[, c('PopulationKA', 'AgeWeeks_Population')]),
                     genesets=baduel_gmt$genesets[c(3,5)],
                     which_test = 'permutation', which_weights = 'loclin',
                     n_perm=1000, preprocessed = TRUE)

  set.seed(54321)
  Cold <- dgsa_seq(exprmat=log2(expr_norm_corr+1),
                   covariates=apply(as.matrix(design[, c('Intercept', 'AgeWeeks', 'PopulationKA', 'AgeWeeks_Population')]), drop=FALSE), 2, as.numeric),
                   variables2test=as.matrix(design[, c('Vernalized', 'Vernalized_Population')]),
                   genesets=baduel_gmt$genesets[c(3,5)],
                   which_test = 'permutation', which_weights = 'loclin',
                   n_perm=1000, preprocessed = TRUE)
}```
**Differential expression analysis of RNA-seq data through a variance component test**

**Description**

Wrapper function for gene-by-gene association testing of RNA-seq data

**Usage**

```r
dear_seq(
  exprmat = NULL,
  object = NULL,
  covariates = NULL,
  variables2test = NULL,
  sample_group = NULL,
  weights_var2test_condi = (which_test != "permutation"),
  cov_variables2test_eff = NULL,
  which_test = c("permutation", "asymptotic"),
  which_weights = c("loclin", "voom", "none"),
  n_perm = 1000,
  progressbar = TRUE,
  parallel_comp = TRUE,
  nb_cores = parallel::detectCores(logical = FALSE) - 1,
  preprocessed = FALSE,
  gene_based_weights = FALSE,
  bw = "nrd",
  kernel = c("gaussian", "epanechnikov", "rectangular", "triangular", "biweight",
             "tricube", "cosine", "optcosine"),
  transform = TRUE,
  padjust_methods = c("BH", "BY", "holm", "hochberg", "hommel", "bonferroni"),
  lowess_span = 0.5,
  R = NULL,
  adaptive = TRUE,
  max_adaptive = 64000,
  homogen_traj = FALSE,
  na.rm_dearseq = TRUE
)
```

**Arguments**

- `exprmat`: a numeric matrix of size G x n containing the raw RNA-seq counts or preprocessed expressions from n samples for G genes. Default is NULL, in which case object must not be NULL.
- `object`: an object that can be either a `SummarizedExperiment`, an `ExpressionSet`, a `DESeqDataSet`, or a `DGEList`. Default is NULL, in which case exprmat must not be NULL.
covariates

- If exprmat is specified as a matrix: then covariates must be a numeric matrix of size \( n \times p \) containing the model covariates for \( n \) samples (design matrix). Usually, its first column is the intercept (full of 1s).
- If object is specified: then covariates must be a character vector of length \( p \) containing the colnames of the design matrix given in object.

If covariates is NULL (the default), then it is just the intercept.

variables2test

- If exprmat is specified as a matrix: a numeric design matrix of size \( n \times K \) containing the \( K \) variables to be tested.
- If object is specified: then variables2test must be a character vector of length \( K \) containing the colnames of the design matrix given in object.

sample_group

A vector of length \( n \) indicating whether the samples should be grouped (e.g. paired samples or longitudinal data). Coerced to be a factor. Default is NULL in which case no grouping is performed.

weights_var2test_condi

A logical flag indicating whether heteroscedasticity weights computation should be conditional on both the variables to be tested variables2test and on the covariates, or on covariates alone. Default is TRUE for the asymptotic test (in which case conditional means are estimated conditionally on both variables2test and covariates), and FALSE for the permutation test (in which case conditional means are estimated conditionally on only the covariates).

cov_variables2test_eff

A matrix of size \( K \times K \) containing the covariance matrix of the \( K \) random effects. Only used if homogen_traj is FALSE. Default assume diagonal correlation matrix, i.e. independence of random effects.

which_test

A character string indicating which method to use to approximate the variance component score test, either 'permutation' or 'asymptotic'. Default is 'permutation'.

which_weights

A character string indicating which method to use to estimate the mean-variance relationship weights. Possibilities are 'loclin', 'voom' or 'none' (in which case no weighting is performed). Default is 'loclin'. See sp_weights and voom_weights for details.

n_perm

The number of perturbations. Default is 1000

progressbar

Logical indicating whether a progressBar should be displayed when computing permutations (only in interactive mode).

parallel_comp

A logical flag indicating whether parallel computation should be enabled. Only Linux and MacOS are supported, this is ignored on Windows. Default is TRUE.

nb_cores

An integer indicating the number of cores to be used when parallel_comp is TRUE. Default is parallel::detectCores(logical=FALSE) - 1.

preprocessed

A logical flag indicating whether the expression data have already been preprocessed (e.g. log2 transformed). Default is FALSE, in which case \( y \) is assumed to contain raw counts and is normalized into log(counts) per million.

gene_based_weights

A logical flag used for 'loclin' weights, indicating whether to estimate weights at the gene-level, or rather at the observation-level. Default is FALSE, which is what it should be for gene-wise analysis.
bw a character string indicating the smoothing bandwidth selection method to use. See \texttt{bandwidth} for details. Possible values are 'ucv', 'SJ', 'bcv', 'nrd' or 'nrd0'.

kernel a character string indicating which kernel should be used. Possibilities are 'gaussian', 'epanechnikov', 'rectangular', 'triangular', 'biweight', 'tricube', 'cosine', 'optcosine'. Default is 'gaussian' (NB: 'tricube' kernel corresponds to the loess method).

transform a logical flag used for 'loclin' weights, indicating whether values should be transformed to uniform for the purpose of local linear smoothing. This may be helpful if tail observations are sparse and the specified bandwidth gives suboptimal performance there. Default is TRUE.

adjust\_methods multiple testing correction method used if genesets is a list. Default is 'BH', i.e. Benjamini-Hochberg procedure for controlling the FDR. Other possibilities are: 'holm', 'hochberg', 'hommel', 'bonferroni' or 'BY' (for Benjamini-Yekutieli procedure).

lowess\_span smoother span for the lowess function, between 0 and 1. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness. Only used if which\_weights is 'voom'. Default is 0.5.

R library.size (optional, important to provide if preprocessed = TRUE). Default is NULL

adaptive a logical flag indicating whether adaptive permutation should be performed. Default is TRUE

max\_adaptive The maximum number of permutations considered. Default is 64000

homogen\_traj a logical flag indicating whether trajectories should be considered homogeneous. Default is FALSE in which case trajectories are not only tested for trend, but also for heterogeneity.

na.rm\_dearseq logical: should missing values in y (including NA and NaN) be omitted from the calculations? Default is TRUE.

\textbf{Value}

A list with the following elements:

- which\_test: a character string carrying forward the value of the 'which\_test' argument indicating which test was perform (either 'asymptotic' or 'permutation').
- preprocessed: a logical flag carrying forward the value of the 'preprocessed' argument indicating whether the expression data were already preprocessed, or were provided as raw counts and transformed into log-counts per million.
- n_perm: an integer carrying forward the value of the 'n_perm' argument indicating the number of perturbations performed (NA if asymptotic test was performed).
- genesets: carrying forward the value of the 'genesets' argument defining the gene sets of interest (NULL for gene-wise testing).
• pval: computed p-values. A data.frame with one raw for each each gene set, or for each gene if genesets argument is NULL, and with 2 columns: the first one 'rawPval' contains the raw p-values, the second one contains the FDR adjusted p-values (according to the 'padjust_methods' argument) and is named 'adjPval'.

dgsa_seq

**Time-course Gene Set Analysis**

**Description**

Wrapper function for performing gene set analysis of (potentially longitudinal) RNA-seq data

**Usage**

dgsa_seq(
  exprmat = NULL,
  object = NULL,
  covariates = NULL,
  variables2test,
  weights_var2test_condi = (which_test != "permutation"),
  genesets,
  sample_group = NULL,
cov_variables2test_eff = NULL,
which_test = c("permutation", "asymptotic"),
which_weights = c("loclin", "voom", "none"),
n_perm = 1000,
progressbar = TRUE,
parallel_comp = TRUE,
nb_cores = parallel::detectCores(logical = FALSE) - 1,
preprocessed = FALSE,
gene_based_weights = TRUE,
bw = "nrd",
kernel = c("gaussian", "epanechnikov", "rectangular", "triangular", "biweight",
"tricube", "cosine", "optcosine"),
transform = TRUE,
padjust_methods = c("BH", "BY", "holm", "hochberg", "hommel", "bonferroni"),
lowess_span = 0.5,
R = NULL,
adaptive = TRUE,
max_adaptive = 64000,
homogen_traj = FALSE,
na.rm_gsa_seq = TRUE,
verbose = TRUE
)

Arguments
exprmat a numeric matrix of size G x n containing the raw RNA-seq counts or preprocessed expressions from n samples for G genes. Default is NULL, in which case object must not be NULL.
object an object that can be either a SummarizedExperiment, an ExpressionSet, a DESeqDataSet, or a DGEList. Default is NULL, in which case exprmat must not be NULL.
covariates • If exprmat is specified as a matrix: then covariates must be a numeric matrix of size n x p containing the model covariates for n samples (design matrix). Usually, its first column is the intercept (full of 1s).
• If object is specified: then covariates must be a character vector of length p containing the colnames of the design matrix given in object.
If covariates is NULL (the default), then it is just the intercept.
variables2test • If exprmat is specified as a matrix: a numeric design matrix of size n x K containing the K variables to be tested.
• If object is specified: then variables2test must be a character vector of length K containing the colnames of the design matrix given in object.
weights_var2test_condi a logical flag indicating whether heteroscedasticity weights computation should be conditional on both the variable(s) to be tested phi and on covariate(s) x, or on x alone. Default is TRUE for the asymptotic test (in which case conditional means are estimated conditionally on both variables2test and covariates), and FALSE for the permutation test (in which case conditional means are estimated conditionally on only the covariates).
genesets Can be either:
  • a vector
  • a list
  • a BiocSet object
Can be a vector of index or subscripts that defines which rows of y constitute
the investigated gene set (when only 1 gene set is being tested).
Can also be a list of index (or rownames of y) when several gene sets are tested
at once, such as the first element of a gmt object.
Finally, can also be a BiocSet object
If NULL, then gene-wise p-values are returned.
sample_group a vector of length n indicating whether the samples should be grouped (e.g.
  paired samples or longitudinal data). Coerced to be a factor. Default is NULL
in which case no grouping is performed.
cov_variables2test_eff a matrix of size K x K containing the covariance matrix of the K random effects.
  Only used if homogen_traj is FALSE. Default assume diagonal correlation matrix,
  i.e. independence of random effects.
which_test a character string indicating which method to use to approximate the variance
  component score test, either 'permutation' or 'asymptotic'. Default is 'permutation'.
which_weights a character string indicating which method to use to estimate the mean-variance
  relationship weights. Possibilities are 'loclin', 'voom' or 'none' (in which case
  no weighting is performed). Default is 'loclin'. See sp_weights and
  voom_weights for details.
n_perm the number of perturbations. Default is 1000.
progressbar a logical indicating wether a progressBar should be displayed when computing
  permutations (only in interactive mode).
parallel_comp a logical flag indicating whether parallel computation should be enabled. Only
  Linux and MacOS are supported, this is ignored on Windows. Default is TRUE.
nb_cores an integer indicating the number of cores to be used when parallel_comp is
  TRUE. Default is parallel::detectCores(logical=FALSE) - 1.
preprocessed a logical flag indicating whether the expression data have already been prepro-
  cessed (e.g. log2 transformed). Default is FALSE, in which case y is assumed to
  contain raw counts and is normalized into log(counts) per million.
gene_based_weights a logical flag used for 'loclin' weights, indicating whether to estimate weights
  at the gene-level, or rather at the observation-level. Default is TRUE, and weights
  are then estimated at the gene-level.
bw a character string indicating the smoothing bandwidth selection method to use.
  See bandwidth for details. Possible values are 'ucv', 'SJ', 'bcv', 'nrd' or
  'nrd0'
kernel a character string indicating which kernel should be used. Possibilities are
  'gaussian', 'epanechnikov', 'rectangular', 'triangular', 'biweight',
  'tricube', 'cosine', 'optcosine'. Default is 'gaussian' (NB: 'tricube'
  kernel corresponds to the loess method).
transform

a logical flag used for 'loclin' weights, indicating whether values should be transformed to uniform for the purpose of local linear smoothing. This may be helpful if tail observations are sparse and the specified bandwidth gives suboptimal performance there. Default is `TRUE`.

padjust_methods

multiple testing correction method used if genesets is a list. Default is 'BH', i.e. Benjamini-Hochberg procedure for controlling the FDR. Other possibilities are: 'holm', 'hochberg', 'hommel', 'bonferroni' or 'BY' (for Benjamini-Yekutieli procedure).

lowess_span

smoother span for the lowess function, between 0 and 1. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness. Only used if which_weights is 'voom'. Default is 0.5.

R

library size (optional, important to provide if preprocessed = TRUE). Default is NULL

adaptive

a logical flag indicating whether adaptive permutation should be performed. Default is `TRUE`

max_adaptive

The maximum number of permutations considered. Default is 64000

homogen_traj

a logical flag indicating whether trajectories should be considered homogeneous. Default is `FALSE` in which case trajectories are not only tested for trend, but also for heterogeneity.

na.rm_gsaseq

logical: should missing values in y (including NA and NaN) be omitted from the calculations? Default is `TRUE`.

verbose

logical: should informative messages be printed during the computation? Default is `TRUE`.

Value

A list with the following elements:

- `which_test`: a character string carrying forward the value of the 'which_test' argument indicating which test was performed (either 'asymptotic' or 'permutation').
- `preprocessed`: a logical flag carrying forward the value of the 'preprocessed' argument indicating whether the expression data were already preprocessed, or were provided as raw counts and transformed into log-counts per million.
- `n_perm`: an integer carrying forward the value of the 'n_perm' argument indicating the number of perturbations performed (NA if asymptotic test was performed).
- `genesets`: carrying forward the value of the 'genesets' argument defining the gene sets of interest (NULL for gene-wise testing).
- `pval`: computed p-values. A data.frame with one raw for each each gene set, or for each gene if genesets argument is NULL, and with 2 columns: the first one 'rawPval' contains the raw p-values, the second one contains the FDR adjusted p-values (according to the 'padjust_methods' argument) and is named 'adjPval'.

Description

9 Pathogenesis Based Transcripts (PBT) gene sets specifically related to kidney transplant

Usage

data(PBT_gmt)

Format

a gmt object containing 9 gene sets specific to kidney transplant (see GSA.read.gmt), which is simply a list with the 3 following components:

- genesets: a list of n gene identifiers vectors composing each gene set (each gene set is represented as the vector of the gene identifiers composing it)
- geneset.names: a vector of length n containing the gene set names (i.e. gene sets identifiers)
- geneset.descriptions: a vector of length n containing gene set descriptions (e.g. textual information on their biological function)

Source

http://atagc.med.ualberta.ca/Research/GeneLists

References

Examples

```r
data('PBT_gmt')
PBT_gmt
```

### permPvals

#### Description

Calculates exact p-values for permutation tests when permutations are randomly drawn with replacement. This implementation is based on (slightly adapted) the implementation by Belinda Phipson and Gordon Smyth from the R package `statmod`.

#### Usage

```r
permPvals(nPermSupObs, nPermEff, totalPossibleNPerm)
```

#### Arguments

- `nPermSupObs`: number of permutations that yielded test statistics at least as extreme as the observed data. Can be a vector or an array of values.
- `nPermEff`: number of permutations effectively computed.
- `totalPossibleNPerm`: total number of permutations possible.

#### Value

A vector (or an array, similar to `nperm_supobs`) of exact p-values.

#### Author(s)

Belinda Phipson and Gordon Smyth (adapted by Boris Hejblum)

#### References

#### See Also

`statmod::permp`
Examples

permPvals(10, 100, 1000)

plot.dearseq  

Plot method for dearseq objects

Description

Plot method for dearseq objects

Usage

```r
## S3 method for class 'dearseq'
plot(x, signif_threshold = 0.05, ...)
```

Arguments

- `x`: an object of class `dear_seq`
- `signif_threshold`: a value between 0 and 1 specifying the nominal significance threshold. Default is 0.05.
- `...`: further arguments

Value

A `ggplot` object

Author(s)

Boris Hejblum

plot_hist_pvals  

Plotting raw p-values histogram

Description

Display the histogram of raw p-values for diagnostic plots

Usage

```r
plot_hist_pvals(pvals, binwidth = 0.02)
```
**plot_ord_pvals**

*Arguments*

- `pvals` a vector of raw p-values
- `binwidth` a value specifying the width of the histogram bins. Default is 0.02.

*Value*

- a `ggplot` object

*Author(s)*

Boris Hejblum

*Examples*

```r
#generate fake data
n <- 1000 #number of genes
nr=5 #number of measurements per subject (grouped data)
ni=50 #number of subjects
r <- nr*ni #number of measurements
t <- matrix(rep(1:nr), ni, ncol=1, nrow=r) # the variable to be tested
sigma <- 0.5
x <- matrix(1, ncol=1, nrow=r) #no covariates only intercept
y.tilde <- rnorm(r, sd = sigma)
y <- t(matrix(rnorm(n*r, sd = sqrt(sigma*abs(y.tilde))), ncol=n, nrow=r) +
      matrix(rep(y.tilde, n), ncol=n, nrow=r))

#Run dear_seq()
res_genes <- dear_seq(exprmat=y, covariates=x, variables2test=t,
                      sample_group=rep(1:ni, each=nr),
                      which_test = "asymptotic",
                      which_weights="none", preprocessed=TRUE)

#Plot
plot_hist_pvals(res_genes$pvals$rawPval)
```

---

**plot_ord_pvals**  
*Plot of gene-wise p-values*

*Description*

This function prints the sorted exact p-values along with the Benjamini-Hochberg limit and the 5

*Usage*

```r
plot_ord_pvals(pvals, signif_threshold = 0.05)
```
Arguments

- **pvals**: a vector of length \( n \) containing the raw p-values for each gene
- **signif_threshold**: a value between 0 and 1 specifying the nominal significance threshold. Default is 0.05.

Value

A plot of sorted gene-wise p-values

Examples

```r
# generate fake data
n <- 1000 # number of genes	nr=5 # number of measurements per subject (grouped data)
ni=50 # number of subjects
r <- nr*ni # number of measurements
t <- matrix(rep(1:nr), ni, ncol=1, nrow=r) # the variable to be tested
sigma <- 0.5
x <- matrix(1, ncol=1, nrow=r) # no covariates only intercept
y.tilde <- rnorm(r, sd = sigma)
y <- t(matrix(rnorm(n*r, sd = sqrt(sigma*abs(y.tilde))), ncol=n, nrow=r) +
     matrix(rep(y.tilde, n), ncol=n, nrow=r))

# Run dear_seq()
res_genes <- dear_seq(exprmat=y, covariates=x, variables2test=t,
sample_group=rep(1:ni, each=nr),
which_test = "asymptotic",
which_weights=’none’, preprocessed=TRUE)

# Plot
plot_ord_pvals(res_genes$pvals$rawPval)
```

Description

Display the variability with respect to the level of expression and the associated smoothed estimation of precision weights accounting for heteroscedasticity.

Usage

`plot_weights(x)`
spaghettiPlot1GS

Spaghetti plot for Specific Gene Set

Description

Spaghetti plot for Specific Gene Set

Arguments

x

a list (such as outputed by the functions sp_weights or voom_weights) containing the following components:

- weights: a matrix n × G containing the estimated precision weights
- plot_utilities: a list containing the following elements:
  - reverse_trans: a function encoding the reverse function used for smoothing the observations before computing the weights
  - method: the weight computation method (either "voom" or "loclin")
  - smth: the vector of the smoothed values computed
  - gene_based: a logical indicating whether the computed weights are based on average at the gene level or on individual observations
  - mu: the transformed observed counts or averages
  - v: the observed variability estimates

Value

a ggplot object

Author(s)

Boris Hejblum

Examples

G <- 10000
n <- 12
p <- 2
y <- sapply(1:n, FUN = function(x){rnbinom(n = G, size = 0.07, mu = 200)})
x <- sapply(1:p, FUN = function(x){rnorm(n = n, mean = n, sd = 1)})

if(interactive()){
  w <- sp_weights(y, x, use_phi=FALSE, na.rm = TRUE, gene_based=TRUE)
  plot_weights(w)

  vw <- voom_weights(y, x)
  plot_weights(vw)
}

spaghettiPlot1GS

Spaghetti plot for Specific Gene Set
Usage

spaghettiPlot1GS(
  gs_index,
  gmt,
  expr_mat,
  design,
  var_time,
  var_indiv,
  sampleIdColname,
  var_group = NULL,
  var_subgroup = NULL,
  plotChoice = c("Medians", "Individual"),
  loess_span = 0.75
)

Arguments

gs_index     index of the specific gene set in gmt.
gmt          a list of elements: geneset, geneset.name and geneset.description (see GSA.read.gmt).
expr_mat     a data.frame with numerics of size G x n containing the raw RNA-seq counts from n samples for G genes.
design       a data.frame or DFrame containing the information of each sample (SampleID).
var_time     the time or visit variable contained in design.
var_indiv    the patient variable contained in design data.
sampleIdColname a character string indicating the name of the sample ID variable in design to be matched with the colnames of expr_mat
var_group    a group variable in design data to divide into two facets. Default is NULL.
var_subgroup a subgroup variable in design data to add 2 curves on plot for each subgroup. Default is NULL.
plotChoice   to choose which type of plot (either "Medians", "Individual" or both). Default is c("Medians", "Individual").
loess_span   smoothing span. Default is 0.75.

Value

a ggplot2 plot object

Examples

data(baduel_5gs)
design$Indiv <- design$Population:design$Replicate
design$Vern <- ifelse(design$Vernalized, "Vernalized", "Non-vernalized")

library(ggplot2)
spaghettiPlot1GS(gs_index = 3, gmt = baduel_gmt, expr_mat = log2(expr_norm_corr+1),
  design = design, var_time = AgeWeeks, var_indiv = Indiv,
  sampleIdColname = "sample", var_group=Vern, var_subgroup=Population,
  plotChoice = "Medians", loess_span= 1.5) +
  xlab("Age (weeks)") + guides(color= "none")

---

**sp_weights**

*Non parametric local heteroscedasticity weights*

**Description**

Computes precision weights that account for heteroscedasticity in RNA-seq count data based on non-parametric local linear regression estimates.

**Usage**

```r
sp_weights(
  y,
  x,
  phi = NULL,
  use_phi = TRUE,
  preprocessed = FALSE,
  gene_based = FALSE,
  bw = c("nrd", "ucv", "SJ", "nrd0", "bcv"),
  kernel = c("gaussian", "epanechnikov", "rectangular", "triangular", "biweight",
             "tricube", "cosine", "optcosine"),
  transform = TRUE,
  verbose = TRUE,
  na.rm = FALSE
)
```

**Arguments**

- **y**
  
  A numeric matrix of size $G \times n$ containing the raw RNA-seq counts or preprocessed expression from $n$ samples for $G$ genes.

- **x**
  
  A numeric matrix of size $n \times p$ containing the model covariate(s) from $n$ samples (design matrix).

- **phi**
  
  A numeric design matrix of size $n \times K$ containing the $K$ variable(s) of interest (e.g. bases of time).

- **use_phi**
  
  A logical flag indicating whether conditional means should be conditioned on phi and on covariate(s) x, or on x alone. Default is TRUE in which case conditional means are estimated conditionally on both x and phi.

- **preprocessed**
  
  A logical flag indicating whether the expression data have already been preprocessed (e.g. log2 transformed). Default is FALSE, in which case y is assumed to contain raw counts and is normalized into log(counts) per million.
sp_weights

gene_based  a logical flag indicating whether to estimate weights at the gene-level. Default is FALSE, when weights will be estimated at the observation-level.

bw  a character string indicating the smoothing bandwidth selection method to use. See bandwidth for details. Possible values are 'ucv', 'SJ', 'bcv', 'nrd' or 'nrd0'. Default is 'nrd'.

kernel  a character string indicating which kernel should be used. Possibilities are 'gaussian', 'epanechnikov', 'rectangular', 'triangular', 'biweight', 'tricube', 'cosine', 'optcosine'. Default is 'gaussian' (NB: 'tricube' kernel corresponds to the loess method).

transform  a logical flag indicating whether values should be transformed to uniform for the purpose of local linear smoothing. This may be helpful if tail observations are sparse and the specified bandwidth gives suboptimal performance there. Default is TRUE.

verbose  a logical flag indicating whether informative messages are printed during the computation. Default is TRUE.

na.rm  logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.

Value

a list containing the following components:

• weights: a matrix n x G containing the computed precision weights

• plot_utilities: a list containing the following elements:
  – reverse_trans: a function encoding the reverse function used for smoothing the observations before computing the weights
  – method: the weight computation method ("loclin")
  – smth: the vector of the smoothed values computed
  – gene_based: a logical indicating whether the computed weights are based on average at the gene level or on individual observations
  – mu: the transformed observed counts or averages
  – v: the observed variability estimates

G <- 10000
n <- 12
```
p <- 2
y <- sapply(1:n, FUN = function(x){rnbinom(n = G, size = 0.07, mu = 200)})
x <- sapply(1:p, FUN = function(x){rnorm(n = n, mean = n, sd = 1)})
w <- sp_weights(y, x, use_phi=FALSE, na.rm = TRUE)

summary.dearseq  
Summary method for dearseq objects

Description
Summary method for dearseq objects

Usage
## S3 method for class 'dearseq'
summary(object, signif_threshold = 0.05, ...)

## S3 method for class 'summary.dearseq'
print(x, ...)

Arguments

object  an object of class dear_seq
signif_threshold  a value between 0 and 1 specifying the nominal significance threshold. Default is 0.05.
...  further arguments
x  an object of class 'summary.dearseq'.

Value
a list

Author(s)
Boris Hejblum
vc_score

Computes variance component score test statistics

Description

This function computes the variance component score test statistics.

Usage

vc_score(y, x, indiv, phi, w, Sigma_xi = diag(ncol(phi)), na_rm = FALSE)

Arguments

y   a numeric matrix of dim g \times n containing the raw RNA-seq counts for g genes from n samples.
x   a numeric design matrix of dim n \times p containing the p covariates to be adjusted for.
indiv  a vector of length n containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor.
phi  a numeric design matrix of size n \times K containing the K variables to be tested
w    a vector of length n containing the weights for the n samples.
Sigma_xi a matrix of size K \times K containing the covariance matrix of the K random effects on phi.
na_rm logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.

Value

A list with the following elements:
- score: approximation of the set observed score
- q: observation-level contributions to the score
- q_ext: pseudo-observations used to compute the covariance, taking into account the contributions of OLS estimates
- gene_scores_unscaled: a vector of the approximations of the individual gene scores

Examples

set.seed(123)

## generate some fake data
n <- 100
r <- 12
t <- matrix(rep(1:3), r/3, ncol=1, nrow=r)
sigma <- 0.4
b0 <- 1

# under the null:
b1 <- 0
# under the alternative:
b1 <- 0.7
y.tilde <- b0 + b1*t + rnorm(r, sd = sigma)
y <- t(matrix(rnorm(n*r, sd = sqrt(sigma*abs(y.tilde))), ncol=n, nrow=r) +
  matrix(rep(y.tilde, n), ncol=n, nrow=r))
x <- matrix(1, ncol=1, nrow=r)

# run test
scoreTest <- vc_score(y, x, phi=t, w=matrix(1, ncol=ncol(y), nrow=nrow(y)),

scoreTest$score

---

vc_score_h

*Computes variance component score test statistic for homogeneous trajectories*

---

**Description**

This function computes the variance component score test statistics for homogeneous trajectories.

**Usage**

```r
vc_score_h(y, x, indiv, phi, w, Sigma_xi = diag(ncol(phi)), na.rm = FALSE)
```

**Arguments**

- `y`: a numeric matrix of dim g x n containing the raw or normalized RNA-seq counts for g genes from n samples.
- `x`: a numeric design matrix of dim n x p containing the p covariates to be adjusted for.
- `indiv`: a vector of length n containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor.
- `phi`: a numeric design matrix of size n x K containing the K longitudinal variables to be tested (typically a vector of time points or functions of time).
- `w`: a vector of length n containing the weights for the n samples, corresponding to the inverse of the diagonal of the estimated covariance matrix of y.
- `Sigma_xi`: a matrix of size K x K containing the covariance matrix of the K random effects corresponding to phi.
- `na_rm`: logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.
**Value**

A list with the following elements:

- `score`: approximation of the set observed score
- `q`: observation-level contributions to the score
- `q_ext`: pseudo-observations used to compute covariance taking into account the contributions of OLS estimates
- `gene_scores`: approximation of the individual gene scores

**Examples**

```r
set.seed(123)

## generate some fake data

ng <- 100
nindiv <- 30
nt <- 5
nsample <- nindiv*nt
tim <- matrix(rep(1:nt), nindiv, ncol=1, nrow=nsample)
tim2 <- tim^2
sigma <- 5
b0 <- 10

# under the null:
beta1 <- rnorm(n=ng, 0, sd=0)
# under the (heterogen) alternative:
beta1 <- rnorm(n=ng, 0, sd=0.1)
# under the (homogen) alternative:
beta1 <- rnorm(n=ng, 0.06, sd=0)

y.tilde <- b0 + rnorm(ng, sd = sigma)
y <- t(matrix(rep(y.tilde, nsample), ncol=ng, nrow=nsample, byrow=TRUE) +
     matrix(rep(beta1, each=nsample), ncol=ng, nrow=nsample, byrow=FALSE) *
     matrix(rep(tim, ng), ncol=ng, nrow=nsample, byrow=FALSE) +
     #matrix(rep(beta1, each=nsample), ncol=ng, nrow=nsample, byrow=FALSE) *
     # matrix(rep(tim2, ng), ncol=ng, nrow=nsample, byrow=FALSE) +
     matrix(rnorm(ng*nsample, sd = sigma), ncol=ng, nrow=nsample, byrow=FALSE)
)
myindiv <- rep(1:nindiv, each=nt)
x <- cbind(1, myindiv/2==floor(myindiv/2))
myw <- matrix(rnorm(nsample*ng, sd=0.1), ncol=nsample, nrow=ng)

# run test
score_homogen <- vc_score_h(y, x, phi=tim, indiv=myindiv, w=myw, Sigma_xi= cov(tim))

score_heterogen <- vc_score(y, x, phi=tim, indiv=myindiv, w=myw, Sigma_xi=cov(tim))
```

vc_score_h_perm

Computes variance component score test statistics for homogeneous trajectory and its permuted distribution

Description

This function computes the variance component score test statistics for homogeneous trajectories along with its permuted values for estimating its distribution under the null hypothesis.

Usage

vc_score_h_perm(
  y, x, indiv, phi, w, Sigma_xi = diag(ncol(phi)), na_rm = FALSE, n_perm = 1000, progressbar = TRUE, parallel_comp = TRUE, nb_cores = parallel::detectCores(logical = FALSE) - 1)

Arguments

y a numeric matrix of dim g x n containing the raw or normalized RNA-seq counts for g genes from n samples.

x a numeric design matrix of dim n x p containing the p covariates to be adjusted for.

indiv a vector of length n containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor.
a numeric design matrix of size \( n \times K \) containing the \( K \) longitudinal variables to be tested (typically a vector of time points or functions of time).

- \( w \): a vector of length \( n \) containing the weights for the \( n \) samples, corresponding to the inverse of the diagonal of the estimated covariance matrix of \( y \).

- \( \Sigma_{\xi} \): a matrix of size \( K \times K \) containing the covariance matrix of the \( K \) random effects corresponding to \( \phi \).

- \( \text{na\_rm} \): logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.

- \( \text{n\_perm} \): the number of permutation to perform. Default is 1000.

- \( \text{progressbar} \): logical indicating whether a progress Bar should be displayed when computing permutations (only in interactive mode).

- \( \text{parallel\_comp} \): a logical flag indicating whether parallel computation should be enabled. Only Linux and MacOS are supported, this is ignored on Windows. Default is TRUE.

- \( \text{nb\_cores} \): an integer indicating the number of cores to be used when \( \text{parallel\_comp} \) is TRUE. Default is \( \text{parallel::detectCores(logical=FALSE)} - 1 \).

### Value

A list with the following elements:

- \( \text{score} \): an approximation of the observed set score
- \( \text{scores\_perm} \): a vector containing the permuted set scores
- \( \text{gene\_scores\_unscaled} \): approximation of the individual gene scores
- \( \text{gene\_scores\_unscaled\_perm} \): a list of approximation of the permuted individual gene scores

### Examples

```r
set.seed(123)

## generate some fake data
ng <- 100
nindiv <- 30
nt <- 5
nsample <- nindiv*nt
tim <- matrix(rep(1:nt), nindiv, ncol=1, nrow=nsample)
tim2 <- tim^2
sigma <- 5
b0 <- 10

# under the null:
beta1 <- rnorm(n=ng, 0, sd=0)
# under the (heterogen) alternative:
beta1 <- rnorm(n=ng, 0, sd=0.1)
# under the (homogen) alternative:
beta1 <- rnorm(n=ng, 0.06, sd=0)

y.tilde <- b0 + rnorm(ng, sd = sigma)
```
y <- t(matrix(rep(y.tilde, nsample), ncol=ng, nrow=nsample, byrow=TRUE) +
  matrix(rep(beta1, each=nsample), ncol=ng, nrow=nsample, byrow=FALSE) *
  matrix(rep(tim, ng), ncol=ng, nrow=nsample, byrow=FALSE) +
  matrix(rnorm(ng*nsample, sd = sigma), ncol=ng, nrow=nsample, byrow=FALSE)
)

myindiv <- rep(1:nindiv, each=nt)
x <- cbind(1, myindiv/2==floor(myindiv/2))
myw <- matrix(rnorm(nsample*ng, sd=0.1), ncol=nsample, nrow=ng)

# run test
# We only use few permutations (10) to keep example running time low
# Otherwise one can use n_perm = 1000

score_homogen <- vc_score_h_perm(y, x, phi=tim, indiv=myindiv,
  w=myw, Sigma_xi=cov(tim), n_perm = 10,
  parallel_comp = FALSE)

score_heterogen <- vc_score_perm(y, x, phi=tim, indiv=myindiv,
  w=myw, Sigma_xi=cov(tim), n_perm = 10,
  parallel_comp = FALSE)

scoreTest_homogen <- vc_test_asym(y, x, phi=tim, indiv=rep(1:nindiv, each=nt),
  w=matrix(1, ncol=ncol(y), nrow=nrow(y)),
  Sigma_xi=cov(tim), homogen_traj = TRUE)

scoreTest_heterogen <- vc_test_asym(y, x, phi=tim, indiv=rep(1:nindiv, each=nt),
  w=matrix(1, ncol=ncol(y), nrow=nrow(y)),
  Sigma_xi=cov(tim), homogen_traj = FALSE)

vc_score_perm

Computes variance component score test statistics and its permuted distribution

Description

This function computes the variance component score test statistics along with its permuted values
for estimating its distribution under the null hypothesis.

Usage

vc_score_perm(
  y,
  x,
)
vc_score_perm

indiv,
phi,
w,
Sigma_xi = diag(ncol(phi)),
na_rm = FALSE,
n_perm = 1000,
progressbar = TRUE,
parallel_comp = TRUE,
nb_cores = parallel::detectCores(logical = FALSE) - 1
)

Arguments

y  a numeric matrix of dim g x n containing the raw RNA-seq counts for g genes from n samples
x  a numeric design matrix of dim n x p containing the p covariates to be adjusted for
indiv a vector of length n containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor
phi a numeric design matrix of size n x K containing the K variables to be tested.
w  a vector of length n containing the weights for the n samples.
Sigma_xi a matrix of size K x K containing the covariance matrix of the K random effects on phi
na_rm  logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.
n_perm  the number of permutation to perform. Default is 1000.
progressbar  logical indicating wether a progressBar should be displayed when computing permutations (only in interactive mode).
parallel_comp a logical flag indicating whether parallel computation should be enabled. Only Linux and MacOS are supported, this is ignored on Windows. Default is TRUE.
nb_cores  an integer indicating the number of cores to be used when parallel_comp is TRUE. Default is parallel::detectCores(logical=FALSE) - 1.

Value

A list with the following elements:

- score: an approximation of the observed set score
- scores_perm: a vector containing the permuted set scores
- gene_scores_unscaled: approximation of the individual gene scores
- gene_scores_unscaled_perm: a list of approximations of the permuted individual gene scores
Examples

```r
set.seed(123)

## generate some fake data
n <- 100
r <- 12
t <- matrix(rep(1:3), r/3, ncol=1, nrow=r)
sigma <- 0.4
b0 <- 1

# under the null:
b1 <- 0
# under the alternative:
b1 <- 0.7
y.tilde <- b0 + b1*t + rnorm(r, sd = sigma)
y <- t(matrix(rnorm(n*r, sd = sqrt(sigma*abs(y.tilde))), ncol=n, nrow=r) +
     matrix(rep(y.tilde, n), ncol=n, nrow=r))
x <- matrix(1, ncol=1, nrow=r)

# run test
scoreTest <- vc_score_perm(y, x, phi=t, w=matrix(1, ncol=nrow(y),
                             nrow=nrow(y)),
Sigma_xi=matrix(1), indiv=rep(1:(r/3), each=3),
parallel_comp = FALSE)

scoreTest$score
```

---

### vc_test_asym

**Asymptotic variance component test statistic and p-value**

Description

This function computes an approximation of the variance component test based on the asymptotic distribution of a mixture of $\chi^2$'s using the saddlepoint method from `pchisqsum`, as per Chen & Lumley 20219 CSDA.

Usage

```r
vc_test_asym(
  y,
  x,
  indiv = rep(1, nrow(x)),
  phi,
  w,
  Sigma_xi = diag(ncol(phi)),
  genewise_pvals = FALSE,
  homogen_traj = FALSE,
  na.rm = FALSE
)
```
Arguments

**y**  
a numeric matrix of dim $g \times n$ containing the raw or normalized RNA-seq counts for $g$ genes from $n$ samples.

**x**  
a numeric design matrix of dim $n \times p$ containing the $p$ covariates to be adjusted for.

**indiv**  
a vector of length $n$ containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor.

**phi**  
a numeric design matrix of size $n \times K$ containing the $K$ longitudinal variables to be tested (typically a vector of time points or functions of time).

**w**  
a vector of length $n$ containing the weights for the $n$ samples, corresponding to the inverse of the diagonal of the estimated covariance matrix of $y$.

**Sigma_xi**  
a matrix of size $K \times K$ containing the covariance matrix of the $K$ random effects corresponding to $\phi$.

**genewise_pvals**  
a logical flag indicating whether gene-wise p-values should be returned. Default is FALSE in which case gene set p-value is computed and returned instead.

**homogen_traj**  
a logical flag indicating whether trajectories should be considered homogeneous. Default is FALSE in which case trajectories are not only tested for trend, but also for heterogeneity.

**na.rm**  
logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.

Value

A list with the following elements when the set p-value is computed:

- **set_score_obs**: the approximation of the observed set score
- **set_pval**: the associated set p-value

or a list with the following elements when gene-wise p-values are computed:

- **gene_scores_obs**: vector of approximating the observed gene-wise scores
- **gene_pvals**: vector of associated gene-wise p-values

vc_test_perm  

**Permutation-based variance component test statistic and p-value**

Description

This function computes an approximation of the Variance Component test for a mixture of $\chi^2$s using permutations. This is preferable to the asymptotic approximation for small sample sizes. We rely on exact p-values following Phipson and Smyth, 2010 (see References).

Usage

```r
vc_test_perm(
    y,
    x,
    indiv = rep(1, nrow(x)),
    phi,
    w,
    Sigma_xi = diag(ncol(phi)),
    n_perm = 1000,
    progressbar = TRUE,
    parallel_comp = TRUE,
```
vc_test_perm

```r
nb_cores = parallel::detectCores(logical = FALSE) - 1,
genewise_pvals = FALSE,
adaptive = TRUE,
max_adaptive = 64000,
homogen_traj = FALSE,
na.rm = FALSE
```

**Arguments**

- `y` a numeric matrix of dim G x n containing the raw RNA-seq counts for G genes from n samples.
- `x` a numeric design matrix of dim n x p containing the p covariates to be adjusted for.
- `indiv` a vector of length n containing the information for attributing each sample to one of the studied individuals. Coerced to be a factor.
- `phi` a numeric design matrix of size n x K containing the K variables to be tested
- `w` a vector of length n containing the weights for the n samples.
- `Sigma_xi` a matrix of size K x K containing the covariance matrix of the K random effects.
- `n_perm` the number of perturbations. Default is 1000.
- `progressbar` logical indicating whether a progressBar should be displayed when computing permutations (only in interactive mode).
- `parallel_comp` a logical flag indicating whether parallel computation should be enabled. Only Linux and MacOS are supported, this is ignored on Windows. Default is TRUE.
- `nb_cores` an integer indicating the number of cores to be used when `parallel_comp` is TRUE. Default is `parallel::detectCores(logical=FALSE) - 1`.
- `genewise_pvals` a logical flag indicating whether gene-wise p-values should be returned. Default is FALSE in which case gene-set p-value is computed and returned instead.
- `adaptive` a logical flag indicating whether adaptive permutation should be performed. Default is TRUE
- `max_adaptive` The maximum number of permutations considered. Default is 64000
- `homogen_traj` a logical flag indicating whether trajectories should be considered homogeneous. Default is FALSE in which case trajectories are not only tested for trend, but also for heterogeneity.
- `na.rm` logical: should missing values (including NA and NaN) be omitted from the calculations? Default is FALSE.

**Value**

A list with the following elements when the set p-value is computed:

- `set_score_obs` the approximation of the observed set score
- `set_pval` the associated set p-value

or a list with the following elements when gene-wise p-values are computed:
• gene_scores.obs: vector of approximating the observed gene-wise scores
• gene_pvals: vector of associated gene-wise p-values
• ds_fdr: vector of associated gene-wise discrete false discovery rates

voom_weights

Precision weights accounting for heteroscedasticity in RNA-seq count data

Description

Implementation of the procedure described in Law et al. for estimating precision weights from RNA-seq data.
voom_weights

Usage

voom_weights(y, x, preprocessed = FALSE, lowess_span = 0.5, R = NULL)

Arguments

y  a matrix of size G x n containing the raw RNA-seq counts or preprocessed expressions from n samples for G genes.

x  a matrix of size n x p containing the model covariates from n samples (design matrix).

preprocessed  a logical flag indicating whether the expression data have already been preprocessed (e.g. log2 transformed). Default is FALSE, in which case y is assumed to contain raw counts and is normalized into log(counts) per million.

lowess_span  smoother span for the lowess function, between 0 and 1. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness. Default is 0.5.

R  library.size (optional, important to provide if preprocessed = TRUE). Default is NULL

Value

a vector of length n containing the computed precision weights

### Power for covariance matrices

**Description**

Compute the power of a positive definite symmetric matrix.

**Usage**

```r
x %%^% n
```

**Arguments**

- `x`: a positive definite symmetric matrix
- `n`: a real number

**Value**

A matrix of the same dimensions as `x`
