Package ‘edge’

May 1, 2024

Type Package
Title Extraction of Differential Gene Expression
Date 2015-04-15
Version 2.36.0
Author John D. Storey, Jeffrey T. Leek and Andrew J. Bass
Maintainer John D. Storey <jstorey@princeton.edu>, Andrew J. Bass<br> <ajbass@emory.edu>
biocViews MultipleComparison, DifferentialExpression, TimeCourse, Regression, GeneExpression, DataImport
Description The edge package implements methods for carrying out differential expression analyses of genome-wide gene expression studies. Significance testing using the optimal discovery procedure and generalized likelihood ratio tests (equivalent to F-tests and t-tests) are implemented for general study designs. Special functions are available to facilitate the analysis of common study designs, including time course experiments. Other packages such as sva and qvalue are integrated in edge to provide a wide range of tools for gene expression analysis.

apply_qvalue

Estimate the q-values for a given set of p-values

Description

Runs qvalue on a deSet object.

Usage

apply_qvalue(object, ...)

## S4 method for signature 'deSet'
apply_qvalue(object, ...)

Arguments

object S4 object: deSet
...
Additional arguments for qvalue

Value

deSet object with slots updated by qvalue calculations.

Author(s)

John Storey, Andrew Bass

References

deSet, odp and lrt

Examples

# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$expr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)
# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# Run lrt (or odp) and apply_qvalue
de_lrt <- lrt(de_obj)
de_lrt <- apply_qvalue(de_lrt, fdr.level = 0.05,
pi0.method = "bootstrap", adj=1.2)
summary(de_lrt)

apply_sva

Estimate surrogate variables

Description

Runs sva on the null and full models in deSet. See sva for additional details.

Usage

apply_sva(object, ...)

## S4 method for signature 'deSet'
apply_sva(object, ...)

Arguments

object S4 object: deSet
...
Additional arguments for sva

Value

deSet object where the surrogate variables estimated by sva are added to the full model and null model matrices.

Author(s)

John Storey, Jeffrey Leek, Andrew Bass

References

betaCoef

See Also
deSet, odp and lrt

Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model, 
full.model = full_model)

de_sva <- apply_sva(de_obj)

de_odp <- odp(de_sva, bs.its = 30)
summary(de_odp)
```

---

**betaCoef**  
*Regression coefficients from full model fit*

**Description**

Access the full model fitted coefficients of a deFit object.

**Usage**

```r
betaCoef(object)
```

**Arguments**

- `object` S4 object: deFit

**Value**

betaCoef returns the regression coefficients for the full model fit.
build_models

Generate a deSet object with full and null models

Description

build_models creates a deSet object. The user inputs the full and null models.

Usage

build_models(data, cov, full.model = NULL, null.model = NULL, ind = NULL)

Arguments

data  matrix: gene expression data.
cov  data.frame: the covariates in the study.
full.model  formula: the adjustment and the biological variables of interest.
null.model  formula: the adjustment variables.
ind  factor: individuals sampled in the study. Default is NULL. Optional.
Value

deSet object

Author(s)

John Storey, Andy Bass

See Also

deSet, build_study

Examples

# create ExpressionSet object from kidney dataset
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null.model <- ~sex
full.model <- ~sex + ns(age, df=4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null.model,
full.model = full.model)
Arguments

- **data** (matrix): gene expression data (rows are genes, columns are samples).
- **grp** (vector): group assignment in the study (for K-class studies). Optional.
- **adj.var** (matrix): adjustment variables. Optional.
- **bio.var** (matrix): biological variables. Optional.
- **tme** (vector): time variable in a time course study. Optional.
- **ind** (factor): individual factor for repeated observations of the same individuals. Optional.
- **sampling** (string): type of study. Either "static" or "timecourse". Default is "static".
- **basis.df** (numeric): degrees of freedom of the basis for time course study. Default is 2.
- **basis.type** (string): either "ncs" (natural cubic spline) or "ps" (polynomial spline) basis for time course study. Default is "ncs".

Value

deSet object

Author(s)

John Storey, Andy Bass

See Also

deSet, build_models

Examples

```r
# create ExpressionSet object from kidney dataset
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr

# create deSet object from data
de_obj <- build_study(data = kidexpr, adj.var = sex, tme = age,
sampling = "timecourse", basis.df = 4)
```
deFit-class

The differential expression class for the model fits

Description

Object returned from fit_models containing information regarding the model fits for the experiment.

Slots

- fit.full matrix: containing fitted values for the full model.
- fit.null matrix: containing fitted values for the null model.
- res.full matrix: the residuals of the full model.
- res.null matrix: the residuals of the null model.
- dH.full vector: contains diagonal elements in the projection matrix for the full model.
- beta.coef matrix: fitted coefficients for the full model.
- stat.type string: information on the statistic of interest. Currently, the only options are “lrt” and “odp”.

Methods

- fitNull(deFit) Access fitted data from null model.
- fitFull(deFit) Access fitted data from full model.
- resNull(deFit) Access residuals from null model fit.
- resFull(deFit) Access residuals from full model fit.
- betaCoef(deFit) Access beta coefficients in linear model.
- sType(deFit) Access statistic type of model fitting utilized in function.

Author(s)

John Storey, Jeffrey Leek, Andrew Bass
deSet  

Create a deSet object from an ExpressionSet

Description

Creates a deSet object that extends the ExpressionSet object.

Usage

deSet(object, full.model, null.model, individual = NULL)

## S4 method for signature 'ExpressionSet'
deSet(object, full.model, null.model, 
    individual = NULL)

Arguments

- **object**: S4 object: ExpressionSet
- **full.model**: formula: full model containing the both the adjustment and the biological variables for the experiment.
- **null.model**: formula: null model containing the adjustment variables for the experiment.
- **individual**: factor: information on repeated samples in experiment.

Value

deSet object

Note

It is essential that the null and full models have the same variables as the ExpressionSet phenoType column names.

Author(s)

John Storey, Andrew Bass

See Also

deset.odp and lrt

Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
```
```
cov <- data.frame(sex = sex, age = age)
pDat <- as(cov, "AnnotatedDataFrame")
exp_set <- ExpressionSet(assayData = kidexpr, phenoData = pDat)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- deSet(exp_set, null.model = null_model, full.model = full_model)

# optionally add individuals to experiment, in this case there are 36 individuals that were sampled twice
indSamples <- as.factor(rep(1:36, each = 2))
de_obj <- deSet(exp_set, null.model = null_model, full.model = full_model, ind = indSamples)
summary(de_obj)
```

---

**deSet-class**

*The differential expression class (deSet)*

**Description**

The deSet class extends the ExpressionSet class. While the ExpressionSet class contains information about the experiment, the deSet class contains both experimental information and additional information relevant for differential expression analysis, explained below in Slots.

**Slots**

- `null.model` formula: contains the adjustment variables in the experiment. The null model is used for comparison when fitting the full model.
- `full.model` formula: contains the adjustment variables and the biological variables of interest.
- `null.matrix` matrix: the null model as a matrix.
- `full.matrix` matrix: the full model as a matrix.
- `individual` factor: contains information on which sample is from which individual in the experiment.
- `qvalueObj` S3 object: containing qvalue object. See qvalue for additional details.

**Methods**

- `as(ExpressionSet, "deSet")` Coerce objects of ExpressionSet to deSet.
- `lrt(deSet, ...)` Performs a generalized likelihood ratio test using the full and null models.
- `odp(deSet, ...)` Performs the optimal discovery procedure, which is a new approach for optimally performing many hypothesis tests in a high-dimensional study.
- `kl_clust(deSet, ...)` An implementation of mODP that assigns genes to modules based off of the Kullback-Leibler distance.
`fit_models(deSet, ...)` Fits a linear model to each gene by method of least squares.
`apply_qvalue(deSet, ...)` Applies `qvalue` function.
`apply_sva(deSet, ...)` Applies surrogate variable analysis (`sva`).
`fullMatrix(deSet)` Access and set full matrix.
`nullMatrix(deSet)` Access and set null matrix.
`fullModel(deSet)` Access and set full model.
`nullModel(deSet)` Access and set null model.
`individual(deSet)` Access and set individual slot.
`qvalueObj(deSet)` Access `qvalue` object. See `qvalue`.
`validObject(deSet)` Check validity of `deSet` object.

**Note**

See `ExpressionSet` for additional slot information.

**Author(s)**

**edge**

*Extraction of Differential Gene Expression*

**Description**

The edge package implements methods for carrying out differential expression analyses of genome-wide gene expression studies. Significance testing using the optimal discovery procedure and generalized likelihood ratio tests (equivalent to F-tests and t-tests) are implemented for general study designs. Special functions are available to facilitate the analysis of common study designs, including time course experiments. Other packages such as snm, sva, and qvalue are integrated in edge to provide a wide range of tools for gene expression analysis.

**Author(s)**

John Storey, Jeffrey Leek, Andrew Bass

**Examples**

```r
## Not run:
browseVignettes("edge")

## End(Not run)
```
endotoxin

Gene expression dataset from Calvano et al. (2005) Nature

Description
The data provide gene expression measurements in an endotoxin study where four subjects were given endotoxin and four subjects were given a placebo. Blood samples were collected and leukocytes were isolated from the samples before infusion and at times 2, 4, 6, 9, 24 hours.

Usage
data(endotoxin)

Format
- endoexpr: A 500 rows by 46 columns data frame containing expression values.
- class: A vector of length 46 containing information about which individuals were given endotoxin.
- ind: A vector of length 46 providing indexing measurements for each individual in the experiment.
- time: A vector of length 46 indicating time measurements.

Value
endoxin dataset

Note
The data is a random subset of 500 genes from the full dataset. To download the full data set, go to http://genomine.org/edge/.

References

Examples
library(splines)
# import data
data(endotoxin)
ind <- endotoxin$ind
class <- endotoxin$class
time <- endotoxin$time
endoexpr <- endotoxin$endoexpr
cov <- data.frame(individual = ind, time = time, class = class)
# formulate null and full models in experiment
# note: interaction term is a way of taking into account group effects
mNull <- ~ns(time, df=4, intercept = FALSE) + class
mFull <- ~ns(time, df=4, intercept = FALSE) + ns(time, df=4, intercept = FALSE):class + class

# create deSet object
de_obj <- build_models(endoexpr, cov = cov, full.model = mFull,
                      null.model = mNull, ind = ind)

# Perform ODP/lrt statistic to determine significant genes in study
de_odp <- odp(de_obj, bs.its = 10)
de_lrt <- lrt(de_obj, nullDistn = "bootstrap", bs.its = 10)

# summarize significance results
summary(de_odp)

fitFull

### fitFull

**Fitted data from the full model**

#### Description

Access the fitted data from the full model in a `deFit` object.

#### Usage

```r
fitFull(object)
```

#### Arguments

- **object**: S4 object: `deFit`

#### Value

fitFull returns a matrix of fitted values from full model.

#### Author(s)

John Storey, Andrew Bass

#### See Also

- `fit_models`
Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
                        full.model = full_model)

de_fit <- fit_models(de_obj)

# extract fitted values for full model
fitted_full <- fitFull(de_fit)
```

---

**fitNull**

*Fitted data from the null model*

**Description**

Access the fitted data from the null model in an deFit object.

**Usage**

```r
fitNull(object)
```

## S4 method for signature 'deFit'

```r
fitNull(object)
```

**Arguments**

- `object`  
  S4 object: deFit

**Value**

`fitNull` returns a matrix of fitted values from null model.

**Author(s)**

John Storey, Andrew Bass
See Also

fit_models

Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

de_fit <- fit_models(de_obj)

# extract fitted values from null model
fitted_null <- fitNull(de_fit)
```

Description

`fit_models` fits a model matrix to each gene by using the least squares method. Model fits can be either statistic type "odp" (optimal discovery procedure) or "lrt" (likelihood ratio test).

Usage

```r
fit_models(object, stat.type = c("lrt", "odp"), weights = NULL)
```

arguments

- `object`: S4 object: `deSet`
- `stat.type`: character: type of statistic to be used. Either "lrt" or "odp". Default is "lrt".
- `weights`: matrix: weights for each observation. Default is NULL.
Details

If "odp" method is implemented then the null model is removed from the full model (see Storey 2007). Otherwise, the statistic type has no affect on the model fit.

Value

deFit object

Note

fit_models does not have to be called by the user to use odp, lrt or kl_clust as it is an optional input and is implemented in the methods. The deFit object can be created by the user if a different statistical implementation is required.

**fullMatrix**  
*Matrix representation of full model*

### Description
These generic functions access and set the full matrix for `deSet` object.

### Usage

```r
fullMatrix(object)

fullMatrix(object) <- value
```

```r
## S4 method for signature 'deSet'
fullMatrix(object)

## S4 replacement method for signature 'deSet'
fullMatrix(object) <- value
```

### Arguments

- **object**: S4 object: `deSet`
- **value**: matrix: full model matrix where the columns are the covariates and rows are observations

### Value
`fullMatrix` returns the value of the full model matrix.

### Author(s)
Andrew Bass, John Storey

### See Also
- `deSet`, `fullModel`
Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
                       full.model = full_model)

# extract the full model equation as a matrix
mat_full <- fullMatrix(de_obj)
```

---

**fullModel**

*Full model equation*

**Description**

These generic functions access and set the full model for `deSet` object.

**Usage**

```r
fullModel(object)
fullModel(object) <- value
```

### S4 method for signature 'deSet'

```r
fullModel(object)
```

### S4 replacement method for signature 'deSet'

```r
fullModel(object) <- value
```

**Arguments**

- `object` S4 object: `deSet`
- `value` formula: The experiment design for the full model.

**Value**

the formula for the full model.

full.model = full_model)

# extract out the full model equation
mod_full <- fullModel(de_obj)

# change the full model in the experiment
fullModel(de_obj) <- ~sex + ns(age, df = 2)
```

---

gibson  
*Gene expression dataset from Idaghdour et al. (2008)*

Description

The data provide gene expression measurements in peripheral blood leukocyte samples from three Moroccan groups leading distinct ways of life: desert nomadic (DESERT), mountain agrarian (VILLE), and coastal urban (AGADIR).

Usage

data(gibson)
Format

- batch: Batches in experiment.
- location: Environment/lifestyle of Moroccan Amazigh groups.
- gender: Sex of individuals.
- gibexpr: A 500 rows by 46 columns matrix of gene expression values.

Value

gibson dataset

Note

These data are a random subset of 500 genes from the total number of genes in the original data set. To download the full data set, go to http://genomine.org/de/.

References

Examples

```r
# import
data(gibson)
batch <- gibson$batch
gender <- gibson$gender
location <- gibson$location
gibexpr <- gibson$gibexpr
cov <- data.frame(Batch = batch, Gender = gender, Location = location)

# create deSet for experiment- static experiment
mNull <- ~Gender + Batch
mFull <- ~Gender + Batch + Location

decided <- ~

determine <- build_modules(gibexpr, cov = cov, full.model = mFull, null.model = mNull)

# Perform ODP/lrt statistic to determine significant genes in study
de_odp <- odp(de_obj, bs.its = 10)
de_lrt <- lrt(de_obj, nullDistrn = "bootstrap", bs.its = 10)

# summarize significance results
summary(de_odp)
```
individual

Individuals sampled in experiment

Description

These generic functions access and set the individual slot in deSet.

Usage

individual(object)

individual(object) <- value

## S4 method for signature 'deSet'
individual(object)

## S4 replacement method for signature 'deSet'
individual(object) <- value

Arguments

object deSet
value factor: Identifies which samples correspond to which individuals. Important if the same individuals are sampled multiple times in a longitudinal fashion.

Value

individual returns information regarding distinct individuals sampled in the experiment.

Author(s)

John Storey, Andrew Bass

kidney

Gene expression dataset from Rodwell et al. (2004)

Description

Gene expression measurements from kidney samples were obtained from 72 human subjects ranging in age from 27 to 92 years. Only one array was obtained per individual, and the age and sex of each individual were recorded.

Usage

data(kidney)

Format

- kidcov: A 133 rows by 6 columns data frame detailing the study design.
- kidexpr: A 500 rows by 133 columns matrix of gene expression values, where each row corresponds to a different probe-set and each column to a different tissue sample.
- age: A vector of length 133 giving the age of each sample.
- sex: A vector of length 133 giving the sex of each sample.

Value

kidney dataset

Note

These data are a random subset of 500 probe-sets from the total number of probe-sets in the original data set. To download the full data set, go to http://genomine.org/edge/. The age and sex are contained in kidcov data frame.
References

Examples
# import data
data(kidney)

de_lrt <- lrt(de_obj, nullDistn = "bootstrap", bs.its = 10)
# summarize significance results
summary(de_odp)

kl_clust

Modular optimal discovery procedure (mODP)

Description
kl_clust is an implementation of mODP that assigns genes to modules based on of the Kullback-Leibler distance.

Usage
kl_clust(object, de.fit = NULL, n.mods = 50)

## S4 method for signature 'deSet,missing'
kl_clust(object, de.fit = NULL, n.mods = 50)

## S4 method for signature 'deSet,deFit'
kl_clust(object, de.fit = NULL, n.mods = 50)

Arguments
object S4 object: deSet.
de.fit S4 object: deFit.
n.mods integer: number of modules (i.e., clusters).
**Details**

mODP utilizes a k-means clustering algorithm where genes are assigned to a cluster based on the Kullback-Leibler distance. Each gene is assigned an module-average parameter to calculate the ODP score (See Woo, Leek and Storey 2010 for more details). The mODP and full ODP produce nearly exact results but mODP has the advantage of being computationally faster.

**Value**

A list with the following slots:

- `mu.full`: cluster averaged fitted values from full model.
- `mu.null`: cluster averaged fitted values from null model.
- `sig.full`: cluster standard deviations from full model.
- `sig.null`: cluster standard deviations from null model.
- `n.per.mod`: total members in each cluster.
- `clustMembers`: cluster membership for each gene.

**Note**

The results are generally insensitive to the number of modules after a certain threshold of about \( n.mods \geq 50 \) in our experience. It is recommended that users experiment with the number of modules. If the number of modules is equal to the number of genes then the original ODP is implemented.

---

**lrt**

*Performs F-test (likelihood ratio test using Normal likelihood)*

### Description

*lrt* performs a generalized likelihood ratio test using the full and null models.

### Usage

```
lrt(object, de.fit, nullDistn = c("normal", "bootstrap"), weights = NULL,
    bs.its = 100, seed = NULL, verbose = TRUE, mod.F = FALSE, ...)
```

### Arguments

- **object** S4 object: *deSet*.
- **de.fit** S4 object: *deFit*. Optional.
nullDistn character: either "normal" or "bootstrap". If "normal" then the p-values are calculated using the F distribution. If "bootstrap" then a bootstrap algorithm is implemented to simulate statistics from the null distribution. In the "bootstrap" case, empirical p-values are calculated using the observed and null statistics (see empPvals). Default is "normal".

weights matrix: weights for each observation. Default is NULL.

bs.its integer: number of null statistics generated (only applicable for "bootstrap" method). Default is 100.

seed integer: set the seed value. Default is NULL.

verbose boolean: print iterations for bootstrap method. Default is TRUE.

mod.F boolean: Moderated F-test, recommended for experiments with a small sample size. Default is FALSE.

... Additional arguments for apply_qvalue and empPvals function.

Details

lrt fits the full and null models to each gene using the function fit_models and then performs a likelihood ratio test. The user has the option to calculate p-values a Normal distribution assumption or through a bootstrap algorithm. If nullDistn is "bootstrap" then empirical p-values will be determined from the qvalue package (see empPvals).

Value
deSet object

Author(s)
John Storey, Andrew Bass

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# lrt method
de_lrt <- lrt(de_obj, nullDistn = "normal")

# to generate p-values from bootstrap
de_lrt <- lrt(de_obj, nullDistn = "bootstrap", bs.its = 30)

# input a deFit object directly
de_fit <- fit_models(de_obj, stat.type = "lrt")
de_lrt <- lrt(de_obj, de.fit = de_fit)

# summarize object
summary(de_lrt)

nullMatrix
Matrix representation of null model

Description
These generic functions access and set the null matrix for deSet object.

Usage
nullMatrix(object)
nullMatrix(object) <- value

## S4 method for signature 'deSet'
nullMatrix(object)

## S4 replacement method for signature 'deSet'
nullMatrix(object) <- value

Arguments
object S4 object: deSet
value matrix: null model matrix where columns are covariates and rows are observations
nullModel

Value
	nullMatrix returns the value of the null model matrix.

Author(s)

John Storey, Andrew Bass

Examples

# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# extract the null model as a matrix
mat_null <- nullMatrix(de_obj)

nullModel

Null model equation from deSet object

Description

These generic functions access and set the null model for deSet object.

Usage

nullModel(object)

nullModel(object) <- value

## S4 method for signature 'deSet'
nullModel(object)
nullModel

## S4 replacement method for signature 'deSet'

nullModel(object) <- value

### Arguments

- **object**: S4 object: deSet
- **value**: formula: The experiment design for the null model.

### Value

nullModel returns the formula for the null model.

### Author(s)

John Storey, Andrew Bass

### See Also

deSet

### Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
cov <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# extract the null model equation
mod_null <- nullModel(de_obj)

# change null model in experiment but must update full model
nullModel(de_obj) <- ~1
fullModel(de_obj) <- ~1 + ns(age, df=4)
```
**odp**

---

**The optimal discovery procedure**

---

**Description**

odp performs the optimal discovery procedure, which is a framework for optimally performing many hypothesis tests in a high-dimensional study. When testing whether a feature is significant, the optimal discovery procedure uses information across all features when testing for significance.

**Usage**

```r
odp(object, de.fit, odp.parms = NULL, weights = NULL, bs.its = 100,
     n.mods = 50, seed = NULL, verbose = TRUE, ...)
```

## S4 method for signature 'deSet,missing'

```r
odp(object, de.fit, odp.parms = NULL, weights = NULL, bs.its = 100, n.mods = 50, seed = NULL, verbose = TRUE, ...)
```

## S4 method for signature 'deSet,deFit'

```r
odp(object, de.fit, odp.parms = NULL, weights = NULL, bs.its = 100, n.mods = 50, seed = NULL, verbose = TRUE, ...)
```

**Arguments**

- `object`  
  S4 object: `deSet`

- `de.fit`  
  S4 object: `deFit`. Optional.

- `odp.parms`  
  list: parameters for each cluster. See `kl_clust`.

- `weights`  
  matrix: weights for each observation. Default is NULL.

- `bs.its`  
  numeric: number of null bootstrap iterations. Default is 100.

- `n.mods`  
  integer: number of clusters used in `kl_clust`. Default is 50.

- `seed`  
  integer: set the seed value. Default is NULL.

- `verbose`  
  boolean: print iterations for bootstrap method. Default is TRUE.

- `...`  
  Additional arguments for `qvalue` and `empPvals`.

**Details**

The full ODP estimator computationally grows quadratically with respect to the number of genes. This becomes computationally taxing at a certain point. Therefore, an alternative method called mODP is used which has been shown to provide results that are very similar. mODP utilizes a clustering algorithm where genes are assigned to a cluster based on the Kullback-Leibler distance. Each gene is assigned an module-average parameter to calculate the ODP score and it reduces the computations time to approximately linear (see Woo, Leek and Storey 2010). If the number of clusters is equal to the number of genes then the original ODP is implemented. Depending on the number of hypothesis tests, this can take some time.
Value

`deSet` object

Author(s)

John Storey, Jeffrey Leek, Andrew Bass

`kl_clust`, `build_models` and `deSet`

Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov,
null_model = null_model, full_model = full_model)

# odp method
de_odp <- odp(de_obj, bs.its = 30)

# input a deFit object or ODP parameters ... not necessary
de_fit <- fit_models(de_obj, stat.type = "odp")
de_clust <- kl_clust(de_obj, n.mods = 10)
de_odp <- odp(de_obj, de.fit = de_fit, odp.parms = de_clust,
        bs.its = 30)

# summarize object
summary(de_odp)
```
**Description**

These generic functions access and set the qvalue object in the deSet object.

**Usage**

```r
qvalueObj(object)
qvalueObj(object) <- value
```

```r
## S4 method for signature 'deSet'
qvalueObj(object)

## S4 replacement method for signature 'deSet'
qvalueObj(object) <- value
```

**Arguments**

- `object` S4 object: deSet
- `value` S3 object: qvalue

**Value**

qvalueObj returns a qvalue object.

**Author(s)**

John Storey, Andrew Bass

cov <- data.frame(sex = sex, age = age)
cov <- data.frame(sex = sex, age = age)

# create models
```
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# run the odp method
de_odp <- odp(de_obj, bs.its = 20)

# extract out significance results
qval_obj <- qvalueObj(de_odp)

# run qvalue and assign it to deSet slot
pvals <- qval_obj$pvalues
qval_new <- qvalue(pvals, pfdr = TRUE, fdr.level = 0.1)
qvalueObj(de_odp) <- qval_new

---

resFull  
*Residuals of full model fit*

**Description**

Access the fitted full model residuals in a `deFit` object.

**Usage**

```r
resFull(object)
```

### S4 method for signature 'deFit'
```
resFull(object)
```

**Arguments**

- **object**: S4 object: `deFit`

**Value**

resFull returns a matrix of residuals from full model.

**Author(s)**

John Storey, Andrew Bass

**See Also**

- `fit_models`
Examples

```r
# import data
library(splines)
data(kidney)
age <- kidney$age
sex <- kidney$sex
kidexpr <- kidney$kidexpr
cov <- data.frame(sex = sex, age = age)

# create models
null_model <- ~sex
full_model <- ~sex + ns(age, df = 4)

# create deSet object from data
de_obj <- build_models(data = kidexpr, cov = cov, null.model = null_model,
full.model = full_model)

# run fit_models to get model fits
de_fit <- fit_models(de_obj)

# extract out the full residuals from the model fit
res_full <- resFull(de_fit)
```

---

**resNull**

Residuals of null model fit

**Description**

Access the fitted null model residuals in an deFit object.

**Usage**

```r
resNull(object)
```

```
## S4 method for signature 'deFit'
resNull(object)
```

**Arguments**

- `object` S4 object: deFit

**Value**

resNull returns a matrix of residuals from null model.
