Package ‘flowStats’

March 20, 2024

Type    Package
Title   Statistical methods for the analysis of flow cytometry data
Version 4.14.1
Author  Florian Hahne, Nishant Gopalakrishnan, Alireza Hadj Khodabakhshi, Chao-Jen Wong, Kyongryun Lee
Maintainer Greg Finak <greg@ozette.com>, Mike Jiang <mike@ozette.com>
Description Methods and functionality to analyse flow data that is beyond the basic infrastructure provided by the flowCore package.
Suggests xtable, testthat, openCyto, ggcyto, ggridges
Encoding UTF-8
Depends R (>= 3.0.2)
Imports BiocGenerics, MASS, flowCore (>= 1.99.6), flowWorkspace, ncdfflow(>= 2.19.5), flowViz, fda (>= 2.2.6), Biobase, methods, grDevices, graphics, stats, cluster, utils, KernSmooth, lattice, ks, RColorBrewer, rrcov, corpcor, mnormt, clue
Enhances RBGL, graph
License Artistic-2.0
Lazyload yes

flowStats-package

Statistical methods for flow cytometry data analysis

Description

Functions, methods and classes implementing algorithms for statistical analysis of flow cytometry data. This involves mostly data normalization and automated gating.

Details

Package: flowStats
Type: Package
Version: 1.0
License: Artistic-2.0
Lazyload: yes

Author(s)

Florian Hahne
Maintainers: Mike Jiang <mike@ozette.ai>, Jake Wagner <jpwagner@fhcrc.org>

addName, curv1Filter, character-method

These methods are copied from flowViz to eliminate its dependency on curv1Filter and curv2Filter

Description

These methods are copied from flowViz to eliminate its dependency on curv1Filter and curv2Filter

Usage

```r
## S4 method for signature 'curv1Filter,character'
addName(x, name, data, ...)

## S4 method for signature 'curv1Filter,logical'
addName(x, name, data, ...)

## S4 method for signature 'curv2Filter,character'
addName(x, name, data, ...)

## S4 method for signature 'curv2Filter,logical'
addName(x, name, data, ...)
```
Arguments

x curv1Filter, curv2Filter
name character or logical. Names can be generated by the filter or by the user.
data flowFrame
... other arguments

Value

The methods are called for their side effects. No value is returned.

autoGate

Automated gating of single populations in 2D

Description

This function tries to fit a single norm2Filter based on a rough preselection of the data. This function is considered internal. Please use the API provided by lymphGate.

Usage

autoGate(x, ... , scale = 2.5)

Arguments

x An object of class flowSet
... Named arguments or a list of the ranges used for the initial rough preselection. This gets passed on to rectangleGate, see it’s documentation for details.
scale The scale parameter that gets passed on to norm2Filter.

Details

The flowSet is first filtered using a rectangleGate and the norm2Filter is subsequently fitted to the remaining subset.

Value

A list with items:

x The filtered flowSet.
n2gate The norm2Filter object.
n2gateResults The filterResult after applying the norm2Filter on the flowSet.

Author(s)

Florian Hahne
**BackGating**

See Also

lymphGate, norm2Filter

Examples

```r
library(flowCore)
data(GvHD)
flowStats:::autoGate(GvHD[10:15], "FSC-H"=c(100,500), "SSC-H"=c(0,400))
```

---

**BackGating**

Sample backgating results

---

**Description**

A data frame containing the sub-populations of ITN dataset corresponding to the high-density areas on "FSC" and "SSC" channels. This dataset is yielded by backGating on channel CD3, CD8, and CD4 of the ITN sample data.

**Usage**

```r
data(BackGating)
```

**Source**

Results from executing the following code:

```r
library(flowCore) data(ITN)
flowStats:::backGating(ITN, xy=c("FSC","SSC"), channels=c("CD3","CD8","CD4"))
```

---

**binByRef**

Bin a test data set using bins previously created by probability binning a control dataset

---

**Description**

The bins generated by probability binning a control data set can be applied to a test data set to perform statistical comparisions by methods such as the Chi-squared test or the probability binning statistic.

**Usage**

```r
binByRef(binRes, data)
```
**Arguments**

- `binRes` The result generated by calling the `probBin` function on a control dataset.
- `data` An object of class `flowFrame`

**Value**

An environment containing the matrices for each bin of the test data set

**Author(s)**

Nishant Gopalakrishnan

**See Also**

`plotBins`, `proBin`

**Examples**

```r
library(flowCore)
data(GvHD)
resCtrl<-proBin(GvHD[[1]],200)
resSample<-binByRef(resCtrl,GvHD[[2]])
ls(resSample)
```

**Description**

This function calculates the Probability binning metric proposed by Baggerly et al. The function utilizes the data binned using the `probBin` and `binByRef` functions.

**Usage**

```r
calcPBChiSquare(ctrlRes,sampRes,ctrlCount,sampCount)
```

**Arguments**

- `ctrlRes` The result generated by calling the `probBin` function on a control dataset.
- `sampRes` The result generated by calling the `binByRef` function on a test sample dataset
- `ctrlCount` The number of events in the control sample
- `sampCount` The number of events in the test sample being compared

**Value**

A list containing the statistic, p.value, observed, expected counts and the residuals
**calcPearsonChi**

Pearsons chi-square statistic for comparing the probability binned datasets

**Description**

This function calculates the Pearson's chi-squared statistic for comparing data binned using the `proBin` and `binByRef` functions. Internally, the function utilizes the `chisq.test` function.

**Usage**

```r
calcPearsonChi(ctrlRes, sampRes)
```

**Arguments**

- `ctrlRes` The result generated by calling the `proBin` function on a control dataset.
- `sampRes` The result generated by calling the `byByRef` function on a sample dataset

**Value**

A list containing the statistic, p.value, observed, expected counts and the residuals

**Author(s)**

Nishant Gopalakrishnan

**See Also**

`proBin`, `calcPBChiSquare`
Examples

library(flowCore)
data(GvHD)

# flow frame 1 is treated as control dataset and used to generate bins
resCtrl<-proBin(GvHD[[1]][,c("FSC-H","SSC-H","Time")],200)
plotBins(resCtrl,GvHD[1][,c("FSC-H","SSC-H","Time")],title="Binned control data")

# Same bins are applied to flowFrame 16
resSample<-binByRef(resCtrl,GvHD[[16]][,c("FSC-H","SSC-H","Time")])
stat<-calcPearsonChi(resCtrl,resSample)

curv1Filter-class  

Class "curv1Filter"

Description

Class and constructor for data-driven filter objects that selects high-density regions in one dimension.

Usage

curv1Filter(x, bwFac=1.2, gridsize=rep(401, 2), filterId="defaultCurv1Filter")

Arguments

x  Character giving the name of the measurement parameter on which the filter is supposed to work on. This can also be a list containing a single character scalar for programmatic access.

filterId  An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.

bwFac, gridsize  Numerics of length 1 and 2, respectively, used to set the bwFac and gridsize slots of the object.

Details

Areas of high local density in one dimensions are identified by detecting significant curvature regions. See Duong, T. and Cowling, A. and Koch, I. and Wand, M.P., Computational Statistics and Data Analysis 52/9, 2008 for details. The constructor curv1Filter is a convenience function for object instantiation. Evaluating a curv1Filter results in potentially multiple sub-populations, hence in an object of class multipleFilterResult. Accordingly, curv1Filters can be used to split flow cytometry data sets.

Value

Returns a curv1Filter object for use in filtering flowFrames or other flow cytometry objects.
Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

bwFac: Object of class "numeric". The bandwidth factor used for smoothing of the density estimate.
gridsize: Object of class "numeric". The size of the bins used for density estimation.
parameters: Object of class "character", describing the parameter used to filter the flowFrame.
filterId: Object of class "character", referencing the filter.

Objects from the Class

Objects can be created by calls of the form new("curvFilter", ...) or using the constructor curv1Filter. Using the constructor is the recommended way of object instantiation:

Methods

%in% signature(x = "flowFrame", table = "curv1Filter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the filter methods.
show signature(object = "curv1Filter"): Print information about the filter.

Note

See the documentation in the flowViz package for plotting of curv1Filters.

Author(s)

Florian Hahne

See Also

curv2Filter, flowFrame, flowSet, filter for evaluation of curv1Filters and split for splitting of flow cytometry data sets based on that.

Examples

library(flowStats)
library(flowCore)
## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Create directly. Most likely from a command line
curv1Filter("FSC-H", filterId="myCurv1Filter", bwFac=2)
## To facilitate programmatic construction we also have the following
c1f <- curv1Filter(filterId="myCurv1Filter", x=list("FSC-H"), bwFac=2)

## Filtering using curv1Filter
fres <- filter(dat, c1f)
fres
summary(fres)
names(fres)

## The result of curv1 filtering are multiple sub-populations
## and we can split our data set accordingly
split(dat, fres)

## We can limit the splitting to one or several sub-populations
split(dat, fres, population="rest")
split(dat, fres, population=list(keep=c("peak 2", "peak 3")))

---

**curv2Filter-class**  
*Class "curv2Filter"*

### Description

Class and constructor for data-driven *filter* objects that selects high-density regions in two dimensions.

### Usage

```r
curv2Filter(x, y, filterId="defaultCurv2Filter", bwFac=1.2, gridsize=rep(151, 2))
```

### Arguments

- **x, y**  
  Characters giving the names of the measurement parameter on which the filter is supposed to work on. *y* can be missing in which case *x* is expected to be a character vector of length 2 or a list of characters.

- **filterId**  
  An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.

- **bwFac, gridsize**  
  Numerics of length 1 and 2, respectively, used to set the bwFac and gridsize slots of the object.
Details

Areas of high local density in two dimensions are identified by detecting significant curvature regions. See Duong, T. and Cowling, A. and Koch, I. and Wand, M.P., Computational Statistics and Data Analysis 52/9, 2008 for details. The constructor `curv2Filter` is a convenience function for object instantiation. Evaluating a `curv2Filter` results in potentially multiple sub-populations, an hence in an object of class `multipleFilterResult`. Accordingly, `curv2Filters` can be used to split flow cytometry data sets.

Value

Returns a `curv2Filter` object for use in filtering `flowFrames` or other flow cytometry objects.

Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

- **bwFac**: Object of class "numeric". The bandwidth factor used for smoothing of the density estimate.
- **gridsize**: Object of class "numeric". The size of the bins used for density estimation.
- **parameters**: Object of class "character", describing the parameters used to filter the `flowFrame`.
- **filterId**: Object of class "character", referencing the filter.

Objects from the Class

Objects can be created by calls of the form `new("curv2Filter", ...)` or using the constructor `curv2Filter`. The constructor is the recommended way of object instantiation:

Methods

- **%in%** signature(x = "flowFrame", table = "curv2Filter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.
- **show** signature(object = "curv2Filter"): Print information about the filter.

Note

See the documentation in the `flowViz` package for plotting of `curv2Filters`.

Author(s)

Florian Hahne
curvPeaks

Parse curv1Filter output

Description

Parse the output of curv1Filter and find modes and midpoints of the high-density regions. This function is considered to be internal.

Usage

curvPeaks(x, dat, borderQuant = 0.01, n = 201, from, to, densities=NULL)
density1d

Arguments

- **x**: A `multipleFilterResult` produced by a `curv1Filter` operation.
- **dat**: The corresponding `flowFrame`.
- **borderQuant**: A numeric in $[0, 1]$ giving the extreme quantiles for which high-density regions are ignored.
- **n, from, to**: Arguments are passed on to `density`.
- **densities**: The optional y values of the density estimate computed for the respective data.

Value

A list with items

- **peaks**: x and y locations of the modes of the regions in the density estimates.
- **regions**: the left and right margins of the regions.
- **midpoints**: the mean of regions.
- **regPoints**: x and y locations of the outline of the significant density regions.
- **densFuns**: an approximation function of the density estimate

Author(s)

Florian Hahne

See Also

`landmarkMatrix`

Examples

```r
library(flowCore)
data(GvHD)
tmp <- filter(GvHD[[10]], curv1Filter("FSC-H"))
res <- flowStats:::curvPeaks(tmp, exprs(GvHD[[10]]), "FSC-H")
```

---

density1d

*Find most likely separation between positive and negative populations in 1D*

Description

The function tries to find a reasonable split point between the two hypothetical cell populations "positive" and "negative". This function is considered internal, please use the API provided by `rangeGate`.
density1d(x, stain, alpha = "min", sd = 2, plot = FALSE, borderQuant = 0.1, absolute = TRUE, inBetween = FALSE, refLine=NULL,rare=FALSE,bwFac=1.2 ,sig=NULL,peakNr=NULL, ...)  

**Arguments**

- **x**: A `flowSet` or `flowFrame`.  
- **stain**: A character scalar giving the flow parameter for which to compute the separation.  
- **alpha**: A tuning parameter that controls the location of the split point between the two populations. This has to be a numeric in the range [0, 1], where values closer to 0 will shift the split point closer to the negative population and values closer to 1 will shift towards the positive population. Additionally, the value of `alpha` can be "min", in which case the split point will be selected as the area of lowest local density between the two populations.  
- **sd**: For the case where there is only a single population, the algorithm falls back to estimating the mode of this population and a robust measure of the variance of its distribution. The `sd` tuning parameter controls how far away from the mode the split point is set.  
- **plot**: Create a plot of the results of the computation.  
- **borderQuant**: Usually the instrument is set up in a way that the positive population is somewhere on the high end of the measurement range and the negative population is on the low end. This parameter allows to disregard populations with mean values in the extreme quantiles of the data range. Its value should be in the range [0, 1].  
- **absolute**: Logical controlling whether to classify a population (positive or negative) relative to the theoretical measurement range of the instrument or the actual range of the data. This can be set to `TRUE` if the alignment of the measurement range is not optimal and the bulk of the data is on one end of the theoretical range.  
- **inBetween**: Force the algorithm to put the separator in between two peaks. If there are more than two peaks, this argument is ignored.  
- **refLine**: Either `NULL` or a numeric of length 1. If `NULL`, this parameter is ignored. When it is set to a numeric, the minor sub-population (if any) below this reference line will be ignored while determining the separator between positive and negative.  
- **rare**: Either `TRUE` or `FALSE`, assumes that there is one major peak, and that the rare positive population is to the right of it. Uses a robust estimate of mean and variance to gate the positive cells.  
- **bwFac**: The bandwidth for smoothing the density estimate. User-tunable  
- **sig**: A value of c(NULL,"L","R"), when sig is not NULL, use the half (left or right) of signal to estimate the std and mean.  
- **peakNr**: when peakNr is not NULL, drop the less significant peaks by their heights  
- **...**: Further arguments.
density1d

Details

The algorithm first tries to identify high density regions in the data. If the input is a flowSet, density regions will be computed on the collapsed data, hence it should have been normalized before (see warpSet for one possible normalization technique). The high density regions are then classified as positive and negative populations, based on their mean value in the theoretical (or absolute if argument absolute=TRUE) measurement range. In case there are only two high-density regions the lower one is usually classified as the negative populations, however the heuristics in the algorithm will force the classification towards a positive population if the mean value is already very high. The absolute and borderQuant arguments can be used to control this behaviour. The split point between populations will be drawn at the value of minimum local density between the two populations, or, if the alpha argument is used, somewhere between the two populations where the value of alpha forces the point to be closer to the negative (0 - 0.5) or closer to the positive population (0.5 - 1).

If there is only a single high-density region, the algorithm will fall back to estimating the mode of the distribution (hubers) and a robust measure of it’s variance and, in combination with the sd argument, set the split point somewhere in the right or left tail, depending on the classification of the region.

For more than two populations, the algorithm will still classify each population into positive and negative and compute the split point between those clusters, similar to the two population case.

Value

A numeric indicating the split point between positive and negative populations.

Author(s)

Florian Hahne

See Also

warpSet, rangeGate

Examples

```r
library(flowCore)
data(GvHD)
dat <- GvHD[pData(GvHD)$Patient==10]
dat <- transform(dat, "FL4-H"=asinh("FL4-H"), "FL3-H"=asinh("FL3-H"))
d <- flowStats:::density1d(dat, "FL4-H", plot=TRUE)
if(require(flowViz))
densityplot(~"FL4-H", dat, refline=d)

## tweaking the location
flowStats:::density1d(dat, "FL4-H", plot=TRUE, alpha=0.8)

## only a single population
flowStats:::density1d(dat, "FL3-H", plot=TRUE)
flowStats:::density1d(dat, "FL3-H", plot=TRUE, sd=2)
```
ellipse

Description
convert ellipse from cov/mu to points used to plot priors

Usage
ellipse(cov, centre, level = 0.95)

fdPar

The version of fdPar from fda 2.4.0 because the new API changes the output. (specifically res$fd$coefs) and thus breaks the landmarkreg call.

Description
The version of fdPar from fda 2.4.0 because the new API changes the output. (specifically res$fd$coefs) and thus breaks the landmarkreg call.

Usage
fdPar(fdobj = NULL, Lfdobj = NULL, lambda = 0, estimate = TRUE, penmat = NULL)

Arguments
fdobj functional data object, functional basis object, a functional parameter object or a matrix. If it a matrix, it is replaced by fd(fdobj). If class(fdobj) == 'basisfd', it is converted to an object of class fd with a coefficient matrix consisting of a single column of zeros.

Lfdobj either a nonnegative integer or a linear differential operator object. If NULL, Lfdobj depends on fdobj[['basis']][['type']]
  • bspline Lfdobj <- int2Lfd(max(0, norder-2)), where norder = norder(fdobj)
  • fourier Lfdobj = a harmonic acceleration operator: Lfdobj <- vec2Lfd(c(0, (2*pi/diff(rng))'^2, rng) where rng = fdobj[['basis']][['rangeval']].
  • anything else Lfdobj <- int2Lfd(0)

lambda a nonnegative real number specifying the amount of smoothing to be applied to the estimated functional parameter.

estimate not currently used.

penmat a roughness penalty matrix. Including this can eliminate the need to compute this matrix over and over again in some types of calculations.
**flowClust2Prior**

Generate a prior specification based on a flowClust model. This function generates a prior specification based on a flowClust fit object. It can be passed to a second round of flowClust() with `usePrior="yes"`. The prior could be estimated from a single sample, for example, and then used to speed up the convergence for other samples.

**Usage**

```r
flowClust2Prior(x, kappa, Nt = NULL, addCluster = NULL)
```

**Arguments**

- **x**: a flowClust fit object
- **kappa**: is the fraction of equivalent observations by which to weight this prior relative to the flowClust model.
- **Nt**: the number of total equivalent observation
- **addCluster**: not currently supported

---

**gate_singlet**

Creates a singlet polygon gate using the prediction bands from a robust linear model.

**Description**

We construct a singlet gate by applying a robust linear model with `rlm`. By default, we model the forward-scatter height (FSC-H) as a function of forward-scatter area (FSC-A). If sidescatter is given, forward-scatter height is as a function of area + sidescatter + sidescatter / area.

**Usage**

```r
gate_singlet(
  x,
  area = "FSC-A",
  height = "FSC-H",
  sidescatter = NULL,
  prediction_level = 0.99,
  subsample_pct = NULL,
)```
wider_gate = FALSE,
filterId = "singlet",
maxit = 5,
...
)
singletGate(
  x,
  area = "FSC-A",
  height = "FSC-H",
  sidescatter = NULL,
  prediction_level = 0.99,
  subsample_pct = NULL,
  wider_gate = FALSE,
  filterId = "singlet",
  maxit = 5,
  ...
)

Arguments

x          a flowFrame object
area       character giving the channel name that records the signal intensity as peak area
height     character giving the channel name that records the signal intensity as peak height
sidescatter character giving an optional channel name for the sidescatter signal. By default, ignored.
prediction_level a numeric value between 0 and 1 specifying the level to use for the prediction bands
subsample_pct a numeric value between 0 and 1 indicating the percentage of observations that should be randomly selected from x to construct the gate. By default, no subsampling is performed.
wider_gate  logical value. If TRUE, the prediction bands used to construct the singlet gate use the robust fitted weights, which increase prediction uncertainty, especially for large FSC-A. This leads to wider gates, which are sometimes desired.
filterId    the name for the filter that is returned
maxit       the limit on the number of IWLS iterations passed to rlm
...         additional arguments passed to rlm

Details

Because rlm relies on iteratively reweighted least squares (IRLS), the runtime to construct a singlet gate is dependent in part on the number of observations in x. To improve the runtime, we provide an option to subsample randomly a subset of x. A percentage of observations to subsample can be given in subsample_pct. By default, no subsampling is applied.
Value

a polygonGate object with the singlet gate

Examples

```r
## Not run:
# fr is a flowFrame
sg <- gate_singlet(fr, area = "FSC-A", height = "FSC-H")
sg
# plot the gate
xyploid("FSC-H ~ FSC-A", fr, filter = sg)
## End(Not run)
```

---

gaussNorm

Per-channel normalization based on landmark registration

Description

This function normalizes a set of flow cytometry data samples by identifying and aligning the high density regions (landmarks or peaks) for each channel. The data of each channel is shifted in such a way that the identified high density regions are moved to fixed locations called base landmarks.

Usage

gaussNorm (flowset, channel.names, max.lms=2, base.lms=NULL, peak.density.thr=0.05, peak.distance.thr=0.05, debug=FALSE, fname='')

Arguments

- `flowset`: A flowSet.
- `channel.names`: A character vector of flow parameters in flowset to be normalized.
- `max.lms`: A numeric vector of the maximum number of base landmarks to be used for normalizing each channel. If it has only one value that will be used as the maximum number of base landmarks for all the channels.
- `base.lms`: A list of vector for each channel that contains the base landmarks for normalizing that channel. If not specified the base landmarks are computed from the set of extracted landmarks.
- `peak.density.thr`: The peaks with density value less than "peak.density.thr times maximum peak density" are discarded.
- `peak.distance.thr`: The sequences of peaks that are located closer than "peak.distance.thr times range of data" are identified. Then for each sequence only one peak (the one with the highest intensity value) is used as a landmark. In other words no two landmarks are located closer than "peak.distance.thr times range of data" to each other.
gpaSet

Multi-dimensional normalization of flow cytometry data

Description

This function performs a multi-dimensional normalization of flow cytometry data (flowSets) using a generalized Procrustes analysis (GPA) method.

detailLogical. Forces the function to draw before and after normalization plots for each sample. The plot of the i-th sample is stored in paste(fname, i) file.

fnameThe pre- and post- normalization plots of the i-th sample is stored in paste(fname, i) file if debug is set to TRUE. If default value is used the plots are drawn on separate X11 windows for each sample. In this case, the function waits for a user input to draw the plots for the next sample.

Details

Normalization is archived in three phases: (i) identifying high-density regions (landmarks) for each flowFrame in the flowSet for a single channel; (ii) computing the best matching between the landmarks and a set of fixed reference landmarks for each channel called base landmarks; (iii) manipulating the data of each channel in such a way that each landmark is moved to its matching base landmark. Please note that this normalization is on a channel-by-channel basis. Multiple channels are normalized in a loop.

Value

A list with items flowset: normalized flowSet. confidence: a confidence measure of the normalization procedure.

Author(s)

Alireza Hadj Khodabakhshi

Examples

library(flowCore)
data(ITN)
dat <- transform(ITN, "CD4"=asinh(CD4), "CD3"=asinh(CD3), "CD8"=asinh(CD8))
lg <- lymphGate(dat, channels=c("CD3", "SSC"), preselection="CD4", scale=1.5)
dat <- Subset(dat, lg)
datr <- gaussNorm(dat, "CD8")$flowset
if(require(flowViz)){
  d1 <- densityplot(~CD8, dat, main="original", filter=curv1Filter("CD8"))
  d2 <- densityplot(~CD8, datr, main="normalized", filter=curv1Filter("CD8"))
  plot(d1, split=c(1,1,2,1))
  plot(d2, split=c(2,1,2,1), newpage=FALSE)
}
gpaSet

Usage

gpaSet(x, params, register="backgating", bgChannels=NULL, 
bg=NULL, rotation_only=TRUE, 
downweight.missingFeatures=FALSE, thres.sigma=2.5, 
show.workflow=FALSE, 
ask=names(dev.cur())!="pdf")

Arguments

x A flowSet.
params A character vector of length 2 describing the channels of interest.
register A character indicating the method to be used for identifying features. Available 
method only includes “backgating” at the point.
bgChannels A character vector indicating the channels used for backgating. If NULL, backGating 
will find the appropriate backgating channels.
bg A data frame as the returning value of the backGating function. If not NULL, 
gpaSet will skip the backGating process and use the given data frame to extract 
potential features.
rotation.only Logical for coarsing a reflection matrix to a rotation matrix.
downweight.missingFeatures Logical. If TRUE, the missing features, labeled as bogus features, are down-
weighted to zero. See details.
thres.sigma A numerical value indicating the threshold of where to cut the tree, e.g., as 
resulting from diana, into several clusters. It is default to 2.5 sigma of the 
distribution of the heights of the cluster points.
show.workflow Logical. If TRUE, the workflow of gpaSet will be displayed.
ask Logical. If TRUE, the display operates in interactive mode.

Details

Normalization is achieved by first identifying features for each flowFrame in the flowSet for des-
ignated channels using backgating, subsequently labeling features, and finally aligning the features 
to a reference feature in the sense of minimizing the Frobenus norm of

$$ ||sF Q - \bar{F}||,$$

where $s$ is a scalar, $Q$ a rotational matrix, $F$ the matrix of features, and $\bar{F}$ the reference feature. Both $s$ and $Q$ are solved by using singular value decomposition (SVD).

Note that if feature $F_{ij}$ is missing, it is given a bogus value as $\bar{F}_{ij}$.
If downweight.missingFeatures is TRUE, the cost function becomes

$$ ||sW_0 F Q - W_0 \bar{F}||,$$

where the weighting function $W_0$ is zero if the corresponding feature is bogus.
Value

The normalized flowSet with "GPA" attribute.

idFeaturesByBackgating

(idFeaturesByBackgating)

(Internal use only) Identify features of flow cytometry data using backgating

Description
Identify and labeling significant features using divisive clustering method such as diana.

Usage
idFeaturesByBackgating(bg, nDim, thres.sigma=2.5, lambda=0.1,
  reference.method="median",
  plot.workflow=FALSE, ask=names(dev.cur())!="pdf")

Arguments
bg A data frame containing subpopulations on channels of interests. Must be a
  returning result from flowStats:::backGating
nDim An integer indicating the length of channels of interest.
thres.sigma An numerical value indicating the threshold at which to cut tree, e.g., as resulting
  from 'diana', into several clusters.
lambda A numerical value indicating the percentage of the potential features that is used
  as a threshold for deciding outlier clusters. The default value is 0.1.
reference.method A character vector indicating the method for computing the reference features. If
  median, the reference feature is defined by the medain of eac cluster of features.
  Valid methods include median and mean only.
plot.workflow Logical. If TRUE, display the workflow of feature identification.
ask Logical. If TRUE, the display operates in interactive mode.
Details

Using the resulting data frame from backGating as potential features, the algorithm follows four major steps: (i) centering the potential features, which yields the returning value TransMatrix, (ii) using diana to compute a clustering of the potential features, (iii) cutting the tree into several clusters, and (iv) accessing outliers and rendering the final registered features with labels.

In step three, the threshold for cutting the tree is computed by

\[ sd \times \text{thres.sigma}, \]

where \( sd \) is the standard deviation of the distribution of the height between entities computed by diana.

A cluster is determined as an outlier if the number of its members is less than the median of the numbers of all clusters’ members times 'lambda'.

Value

- **register**: A list containing registered features for each sample.

iProcrustes

Procrustes analysis. Using singular value decomposition (SVD) to determine a linear transformation to align the points in X to the points in a reference matrix Y.

Description

Based on generalized Procrustes analysis, this function determines a linear transformation (rotation/reflection and scaling) of the points in matrix x to align them to their reference points in matrix xbar. The alignment is carried out by minimizing the distance between the points in x and xbar.

Usage

iProcrustes(x, xbar, rotation.only=TRUE, scalling=TRUE, translate=FALSE)

Arguments

x A numerical matrix to be align to points in xbar, the second argument. The columns represents the coordinates of the points. The matrices x and xbar must have the same dimensions.

xbar A numerical, reference matrix to which points in matrix x are to be aligned.

rotation.only Logical. When rotation.only is TRUE, it allows the function to lose reflection component of the linear transformation. Although it might not give the best-fitting alignment, when dealing with flow cytometry data alignment, a non-reflection transformation is preferred. When rotation.only is FALSE, it allows the function to retain the reflection component.

scalling Logical. When scalling is FALSE, it allows the function to calculate the linear transformation without a scalling factor. That is, the returning scalling factor is set to 1.

translate Logical. Set translate to FALSE when the points in matrices x and xbar are already centralized prior to applying this function. When translate is TRUE, it allows the function to translate the centroid the points in matrix x to that of points in xbar.

Details

Suppose the points in matrix X and \( \bar{X} \) are centralized (meaning their centroids are at the origin). The linear transformation of X for aligning X to its reference matrix \( \bar{X} \), i.e., \( \min \|s X Q - \bar{X}\|_F \), is given by:

\[
Q = V U^T,
\]

and

\[
s = \text{trace}(\bar{X}^T X Q)/\text{trace}(X^T X),
\]

where V and U are the singular value vectors of \( \bar{X}^T X \) (that is, \( \bar{X}^T X = U \Sigma V^T \)), and s is the scalling factor.
iProcrustes

**Value**

A list of the linear transformation with items

- **Q** An orthogonal, rotation/reflection matrix.
- **scal** A scaling factor.
- **T** (optional) A translation vector used to shift the centroid of the points in matrix x to the origin. Returned when translate is TRUE.
- **T.xbar** (optional) Centered xbar (that is, the centroid of the points in xbar is translated to the origin). Returned when translate is TRUE.

Note that the return values of this function do not include the transformed matrix \( scal \times x \times Q \) or \( scal \times (x - IT) \times Q \), where \( T \) is the translation vector and \( I \) is an \( n - by - 1 \) vector with elements 1.

**Source**

Immune Tolerance Network
landmarkMatrix

Compute and cluster high density regions in 1D

Description

This function first identifies high-density regions for each flowFrame in a flowSet and subsequently tries to cluster these regions, yielding the landmarks matrix that needs to be supplied to landmarkreg. The function is considered to be internal.

Usage

landmarkMatrix(data, fres, parm, border=0.05, peakNr=NULL, densities = NULL, n = 201, indices=FALSE)

Arguments

data A flowSet.
fres A list of filterResultList objects generated by a filtering operation using a curv1Filter. Each list item represents the results for one of the flow parameters in parm.
parm Character scalar of flow parameter to compute landmarks for.
border A numeric in \([0,1]\). Ignore all high-density regions with mean values in the extreme percentiles of the data range.
peakNr Force a fixed number of peaks.
densities An optional matrix of y values of the density estimates for the flowSet. If this is not present, density estimates will be calculated by the function.
n Number of bins used for the density estimation.
indices Return matrix of population indices instead of landmark locations. These indices can be used to point into the populations identified by the curv1Filter.

Details

In order to normalize the data using the landmarkreg function in the fda, a set of landmarks has to be computed for each flowFrame in a flowSet. The number of landmarks has to be the same for each frame. This function identifies high-density regions in each frame, computes a simple clustering and returns a matrix of landmark locations. Missing landmarks of individual frames are substituted by the mean landmark location of the respective cluster.

Value

A matrix of landmark locations. Columns are landmarks and rows are flowFrames.

Examples

library(flowCore)
data(GvHD)
tmp <- list("FSC-H"=filter(GvHD[1:3], curv1Filter("FSC-H")))
res <- flowStats::landmarkMatrix(GvHD[1:3], tmp, "FSC-H")

lymphFilter-class  Automated gating of elliptical cell populations in 2D.

Description

Cell populations of roughly elliptical shape in two-dimensional projections are of huge interest in many flow cytometry applications. This function identifies a single such population, potentially from a mixture of multiple populations.

Usage

lymphGate(x, channels, preselection=NULL, scale=2.5, bwFac=1.3,
filterId="defaultLymphGate", plot=FALSE, ...)

Arguments

x  An object of class flowSet.
channels  A character vector of length 2 of valid flow parameters in x.
preselection  Either NULL, in which case this boils down to fitting a regular norm2Filter, a character scalar giving one of the flow parameters in x, or a named list of numerics specifying the initial rough preselection. The latter gets passed on to rectangleGate, see it’s documentation for details.
scale  The scaleFactor parameter that gets passed on to norm2Filter.
bwFac  The bandwidth factor that gets passed on to curv1Filter.
filterId  A character used as filterId.
plot  Logical. Produce plots of filter results
...  Additional arguments.
Details

This algorithm does not apply real mixture modelling, however it is able to identify a single elliptical cell population from a mixture of multiple such populations. The idea is to first define a rough rectangular preselection and, in a second step, fit a bivariate normal distribution to this subset only.

Depending on the value of preselection, the initial rough selection is either

**NULL:** No preselection at all

**character scalar** Preselection based on cells that are positive for a single marker only. This allows for back-gating, for instances by selecting CD4+ T-cells and using this information to back-gate lymphocytes in FSC and SSC. Positive cells are identified using a `curv1Filter`.

**a named list of numerics:** Preselection by a rectangular gate. The items of the list have to be numerics of length one giving the gate boundaries in the respective dimensions.

Value

An `ellipsoidGate` or list of `ellipsoidGate` objects

Extends

Class `parameterFilter`, directly.
Class `concreteFilter`, by class "parameterFilter", distance 2.
Class `filter`, by class "parameterFilter", distance 3.

Slots

See Arguments section for details.

- `preselection`: Object of class character, the name of the flow parameter used for preselection.
- `rectDef`: Object of class list, the initial rectangular selection.
- `scale`: Object of class numeric.
- `bwFac`: Object of class numeric.
- `parameters`: Object of class `parameters`, the flow parameters to operate on.
- `filterId`: Object of class "character", the filter identifier.

Objects from the Class

Objects can be created by calls of the form `new("lymphFilter", parameters, ...)` or using the constructor `lymphFilter`. The constructor is the recommended way of object instantiation.

data(GvHD)
dat <- GvHD[pData(GvHD)$Patient==10]
dat <- transform(dat, "FL4-H"=asinh("FL4-H"))
lg <- lymphGate(dat, channels=c("FSC-H", "SSC-H"), preselection="FL4-H",scale=1.5)

if(require(flowViz))
  xyplot(~SSC-H~FSC-H, dat, filter=lg)
```

Description

Generate a flowClust prior specification from gates and data

Usage

```r
mkPrior(gate, data, nu0, Omega0, ...)
```

## S4 method for signature 'polygonGate,flowFrame,numeric,matrix'
```r
mkPrior(gate, data, nu0, Omega0)
```

## S4 method for signature 'rectangleGate,flowFrame,numeric,matrix'
```r
mkPrior(gate, data, nu0, Omega0)
```

## S4 method for signature 'rectangleGate,flowFrame,missing,missing'
```r
mkPrior(gate, data, nu0 = NA, Omega0 = NA)
```

## S4 method for signature 'polygonGate,flowFrame,missing,missing'
```r
mkPrior(gate, data, nu0 = NA, Omega0 = NA)
```

## S4 method for signature 'list,flowSet,missing,missing'
```r
mkPrior(gate, data, nu0 = NA, Omega0, model.cov = "full", model.means = "full")
```

## S4 method for signature 'missing,flowSet,ANY,missing'
```r
mkPrior(gate, data, nu0 = NA, Omega0, model.cov = "full", model.means = "full")
```

## S4 method for signature 'missing,flowFrame,missing,missing'
```r
mkPrior(gate, data, nu0, Omega0)
```

## S4 method for signature 'list,flowSet,ANY,missing'
```r
mkPrior(gate, data, nu0 = NA, Omega0, model.cov = "full", model.means = "full")
```
Arguments

gate A list of flowCore gates. The gates should represent the SAME population gated across multiple samples.
data A flowSet of the same size as the number of gates above. Each flowFrame in the flowSet should contain the events representing the population in its corresponding gate, i.e. it should be the gated data.

nu0 The nu0 hyperparameter. For estimation from data, it should be nu0=NA.
Omega0 The Omega0 hyperparameter. For estimation from data it can be missing.
... Not currently used.

model.cov, model.means
model names used for cov and means. one of c("full","DE","DU"). "full" is the default.

Details

Construct a prior specification. Generally not called by the user.

Value

Return values depend on the specific method called. Not meant for user consumption.

Author(s)

Greg Finak <gfinak@fhcrc.org>

References

Examples

## The function is currently defined as

```r

```
Arguments

- **x, y**: Characters giving the names of the measurement parameter on which the filter is supposed to work on. *y* can be missing in which case *x* is expected to be a character vector of length 2 or a list of characters.
- **filterId**: An optional parameter that sets the *filterId* slot of this filter. The object can later be identified by this name.
- **scale.factor, n**: Numerics of length 1, used to set the *scale.factor* and *n* slots of the object.
- **method**: Character in *covMcd* or *cov.rob*, used to set the *method* slot of the object.

Details

The filter fits a bivariate normal distribution to the data and selects all events within the Mahalanobis distance multiplied by the *scale.factor* argument. The constructor *norm2Filter* is a convenience function for object instantiation. Evaluating a *curv2Filter* results in an object of class *logicalFilterResult*. Accordingly, *norm2Filters* can be used to subset and to split flow cytometry data sets.

Value

Returns a *norm2Filter* object for use in filtering *flowFrames* or other flow cytometry objects.

Slots

- **method**: One of *covMcd* or *cov.rob* defining method used for computation of covariance matrix.
- **scale.factor**: Numeric vector giving factor of standard deviations used for data selection (all points within *scalefac* standard deviations are selected).
- **n**: Object of class "numeric", the number of events used to compute the covariance matrix of the bivariate distribution.
- **filterId**: Object of class "character" referencing the filter.
- **parameters**: Object of class "ANY" describing the parameters used to filter the *flowFrame* or *flowSet*.

Extends

Class "parameterFilter", directly.

Class "concreteFilter", by class parameterFilter, distance 2.

Class "filter", by class parameterFilter, distance 3.

Objects from the Class

Objects can be created by calls of the form *new("norm2Filter",...)* or using the constructor *norm2Filter*. The constructor is the recommended way.
Methods

%in% signature(x = "flowFrame", table = "norm2Filter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.

show signature(object = "norm2Filter"): Print information about the filter.

Note

See the documentation in the `flowViz` package for plotting of `norm2Filters`.

cov.rob, CovMcd, `filter` for evaluation of `norm2Filters` and `split` and `Subset` for splitting and subsetting of flow cytometry data sets based on that.

Examples

```r
library(flowCore)
## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", 
package="flowCore"))

## Create directly. Most likely from a command line
norm2Filter("FSC-H", "SSC-H", filterId="myCurv2Filter")

## To facilitate programmatic construction we also have the following
n2f <- norm2Filter(filterId="myNorm2Filter", x=list("FSC-H", "SSC-H"), 
scale.factor=2)
n2f <- norm2Filter(filterId="myNorm2Filter", x=c("FSC-H", "SSC-H"), 
scale.factor=2)

## Filtering using norm2Filter
fres <- filter(dat, n2f)
fres
summary(fres)

## The result of norm2 filtering is a logical subset
Subset(dat, fres)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
split(dat, fres)
```
normalize-methods

normalize a GatingSet imported with flowWorkspace, using sequential normalization on the manual gates in the GatingHierarchy.

Description

The method will step through the gating hierarchy in a breadth first search manner and normalize each dimension and gate not explicitly excluded in skipdims, or skipgates. The normalization approach is based on warpSet, but uses sequential normalization to alternately normalize then perform gating of the cell populations. This often helps with feature registration of populations lower in the gating hierarchy. FSC and SSC, as well as time are generally excluded by default. The rule of thumb, is to only normalize a channel in a gate if it is absolutely warranted.

Usage

normalize(data, x, ...)

Arguments

data The GatingSet to be normalized.
x missing. Not used in here.
... Arguments passed to downstream functions.
target: The target sample to normalize the other samples in the gating set to. A character vector. Must match a sample name in x, otherwise NULL will use the mean (average) of the peaks identified in all samples.
populations: A character vector of population names that are to be normalized.
dims: A character vector of parameter names to be normalized.
chunksize: For a memory-efficient implementation of normalization, set the chunksize (an integer), which will perform normalization on chunks of the data of size chunksize.
nPeaks: A list of integer or an integer vector that specifies the expected number of peaks for each sample. Can be omitted to keep all peaks.
bwFac: The bandwidth for density estimation, a numeric. Affects the sensitivity for smoothing and detecting distinct peaks.

Details

This function implements sequential normalization using a GatingSet and a set of manual gates. For each gate in the gating hierarchy, the algorithm checks if the gate should be normalized, and which dimensions in the gate should be normalized. If normalization is warranted, this is performed prior to gating. After gating, the counts for the gate in the GatingSet are updated, and the next gate is processed. This is useful in the application of template gates to data that has staining variability in one or more channels.

Value

Returns a GatingSet of normalized data.
normQA

Normalization quality assessment

Description

Create QA plots for a flow cytometry normalization process.

Usage

```
normQA(data, morph = c("^fsc", "^ssc"),
       channels, odat = NULL, ask = names(dev.cur()) != "pdf",
       grouping = NULL, tag.outliers = FALSE, peaksOnly = TRUE)
```
overton_like

Arguments

data
morph
channels
odat
ask
grouping
tag.outliers
peaksOnly

A character vector of channel names to use for the backgating into the morphological channels.
The channels for which to create plots. Defaults to all normalized channels.
The original data set, always needed if there are no warping functions available.
Ask before creating a new plot.
A grouping variable in data’s phenoData slot.
Logical. Add sample name to outliers in the plots.
Logical. Only use data when a peak was detected in a particular sample. If set to FALSE, a average peak location is estimated.
a normalized flowSet.

Details

This function assumes that the necessary information has been added as attributes to data during the normalization procedure. Depending on the available information, a set of QA plots is generated. Available plots are:
Amount of peak adjustment
Warping functions
Landmark classification confidence
Backgating of peak events in morphological channels

Value

This function is called for its side effect of generating plots.

Author(s)

Florian Hahne

Description

This function computes an Overton-like subtraction of two densities. It calculates the proportion of the reference density that is above a reference

Usage

overton_like(ref, test, twosided = FALSE)
Arguments

- **ref**: The reference channel specified as a vector
- **test**: The test (potentially positive) channel specified as a vector
- **twosided**: boolean flag testing whether the area of the density of the test curve above the reference curve will be calculated on both sides of the mode of the test curve (TRUE) or only on the positive side of the mode (FALSE, default).

Details

The test can be one-sided or two-sided. If one sided, it tests the region of the test density that is above the mode of the reference density. If two-sided it will look at the regions on either side of the mode of the reference density. Densities are computed on a grid of 1024, and appropriately normalized.

Value

numeric value representing the proportion of the area of the test density above the reference density.

Author(s)

Greg Finak

Examples

```r
A = rnorm(10000,mean=1,sd=0.5)
B = rnorm(10000,mean=2,sd=0.5)
overton_like(A,B)
```

plotBins

Plots the probability bins overlaid with flowFrame data

Description

This function is useful in visualizing the differences between the binned control and sample datasets. The bins generated from the control dataset are overlaid with the sample dataset. An optional argument residuals can be used to shade each bin based on a calculated statistical measure of difference between the number of events in each bin.

Usage

```r
plotBins(binRes, data, channels, title, residuals, shadeFactor)
```
**plotPrior**

Plots a flowClust prior over some data.

**Arguments**

- `binRes` The result generated by calling the `probBin` function on a control dataset.
- `data` An object of class `flowFrame` sampled from the dataset.
- `channels` The flow parameters to be plotted. In cases where more than two parameters are binned from the control set, the `plotBins` function plots the projections of the hyperplanes in 2 dimensions.
- `title` Optional title for the plot generated.
- `residuals` A vector of length equal to the number of bins generated that can be used to shade each bin. The residuals from the `calcPearsonChi` function or the `calcPBChiSquare` function can be used to highlight the bins that are different between control and sample datasets.
- `shadeFactor` Optional argument between 0 and 1 that controls the intensity of the shading of bins.

**Author(s)**

Nishant Gopalakrishnan

**See Also**

`probBin, calcPearsonChi, calcPBChiSquare`

**Examples**

```r
library(flowCore)
data(GvHD)
# flow frame 1 is treated as control dataset and used to generate bins
resCtrl <- probBin(GvHD[[1]], 200, channels = c("FSC-H", "SSC-H"))
plotBins(resCtrl, GvHD[[1]], channels = c("FSC-H", "SSC-H"), title = "Binned control data")
# Same bins are applied to flowFrame 16
resSample <- binByRef(resCtrl, GvHD[[16]])
stat <- calcPearsonChi(resCtrl, resSample)
dev.new()
plotBins(resCtrl, data = GvHD[[16]], channels = c("FSC-H", "SSC-H", "Time"), title = "Comparision 1 & 16", residuals = stat$residuals[2], shadeFactor = 0.7)
```

---

**plotPrior**

Plots a flowClust prior over some data.
**Arguments**

- **data**
  On object of class "flowFrame". The data to be plotted.

- **prior**
  An object of class "flowClustPrior", or "flowClustPriorList", returned by a call to mkPrior.

- **dims**
  A character vector of the dimensions to be included in the plot. The dimension names should match column names in the prior and in the flowFrame.

- **...**
  Additional arguments to plotting functions, such as smooth=TRUE/FALSE

**Details**

Generates a plot of a "flowClustPrior" or "flowClustPriorList" object overlaid on some data. Plots the prior means (Mu0), prior covariance of the means (Omega0), and prior sample covariance (Lambda0).

**Value**

Silently returns zero.

**Author(s)**

Greg Finak <gfinak@fhcrc.org>

---

**proBin**

*Probability binning - a metric for evaluating multivariate differences*

**Description**

This function divides the flowframe events into bins such that each bin contains the same number of events. The number of events falling into each bin can then be compared across the control and test samples using statistical methods such as the Chi-squared test.

**Usage**

```r
proBin(m, minEvents=500, channels=NULL)
```

**Arguments**

- **m**
  An object of class `flowFrame`

- **minEvents**
  The minEvents The minimum number of events in each bin. (i.e. the termination criterion for the probability binning algorithm)

- **channels**
  A character vector for the fluorescence channels on which probability binning is to be performed. Defaults is NULL, in which case, all fluorescence channels are used for probability binning. (Time information, if provided in the flowFrame is discarded)
**Details**

The flowSet is first filtered using a rectangleGate and the norm2Filter is subsequently fitted to the remaining subset.

**Value**

A list with items:

- **table**: A data.frame that stores information regarding each node of the tree generated during each stage of the probability binning algorithm. Each row in the table represents a node, the first row representing the original flowFrame matrix. The dataIndx column provides indexes for retrieving the matrices during each stage of the binning process from the environment data. The parent field indicates the row number in the table that holds the parent information for the corresponding node. The left and right columns indicate the row numbers in the table that stores information regarding the children of that particular node. The leaf nodes that hold the binned data can be identified by the nodes with the left of right values of zero (i.e., no children nodes). The visited column is used internally by the algorithm to check if a particular node has been visited during the computation process.

- **data**: An environment in which the matrices generated during each stage of the probability binning process is stored. The matrices stored at the leaf nodes represent the binned events obtained after the stop criterion of minEvents has been achieved. These can be identified by the corresponding dataIndx fields provided by the rows in the table with the left or right column values of zero.

- **limits**: A list containing the the boundaries of each hyperplane generated during probability binning.

- **splitPars**: A data.frame containing two columns splitCol - indicates the column number of the flowFrame, the split was performed. splitMed - The median value which was used as the threshold for splitting the flowFrame. The splitCol and splitMed parameters are utilized by the plotBins and shadeBins functions in visualizing the differences between control and test sample cases.

data(GvHD)
res<--proBin(GvHD[[1]],200,channels=c("FSC-H","SSC-H","FL1-H","FL4-H"))
```
quadrantGate

Automated quad gating

Description
This function tries to find the most likely separation of two-dimensional flow cytometry in four quadrants.

Usage
quadrantGate(x, stains, alpha=c("min", "min"), sd=c(2, 2), plot=FALSE,
    filterId="defaultQuadGate", refLine.1=NULL, refLine.2=NULL
    ,rare=c(FALSE,FALSE)
    ,sig=c(NULL,NULL)
    ,...
)

Arguments
x  A flowSet or flowFrame.
stains  A character vector of length two giving the two flow parameters for which the quad gate is to be computed.
alpha, sd  Tuning factors to control the computation of the gate boundaries. See rangeGate for details.
plot Logical. Produce plots of intermediate results.
filterId  Character, the name assigned to the resulting filter.
refLine.1  Either NULL or a numeric of length 1. If NULL, this parameter is ignored. When it is set to a numeric, the minor sub-population (if any) below this reference line in the first stain channel will be ignored while determining the separator between positive and negative.
refLine.2  Either NULL or a numeric of length 1. If NULL, this parameter is ignored. When it is set to a numeric, the minor sub-population (if any) below this reference line in the second stain channel will be ignored while determining the separator between positive and negative.
rare  logical flags for two channels, Refer to density1d for more details.
sig  parameters for two channels. Refer to density1d for more details.
... Additional arguments

Details
The most likely separation between positive and negative stains for two-dimensional data is computed based on density estimates. Essentially, the gate parameters are first fitted separately for the two parameters and later combined. See the documentation for rangeGate for details. There is a certain amount of heuristics involved in this process. The algorithm can be slightly tweaked using the alpha and sd arguments. Their values will be recycled for the two dimensions unless explicitly given as vectors of length 2.
Value

An object of class `quadGate`.

Author(s)

Florian Hahne

qg
split(dat, qg)
## End(Not run)
```

---

rangeGate

Find most likely separation between positive and negative populations in 1D

Description

The function tries to find a reasonable split point between the two hypothetical cell populations "positive" and "negative".

Usage

```
rangleGate(x, stain, alpha="min", sd=2, plot=FALSE, borderQuant=0.1, absolute=TRUE, filterId="defaultRectangleGate", positive=TRUE, refLine=NULL, simple = FALSE,...)

rangeFilter(stain, alpha="min", sd=2, borderQuant=0.1, filterId="defaultRangeFilter")
```

Arguments

- **x**: A `flowSet` or `flowFrame`.
- **stain**: A character scalar giving the flow parameter for which to compute the separation.
- **alpha**: A tuning parameter that controls the location of the split point between the two populations. This has to be a numeric in the range $[0, 1]$, where values closer to 0 will shift the split point closer to the negative population and values closer to 1 will shift towards the positive population. Additionally, the value of `alpha` can be "min", in which case the split point will be selected as the area of lowest local density between the two populations.
- **sd**: For the case where there is only a single population, the algorithm falls back to estimating the mode of this population and a robust measure of the variance of it distribution. The `sd` tuning parameter controls how far away from the mode the split point is set.
- **plot**: Create a plot of the results of the computation.
- **borderQuant**: Usually the instrument is set up in a way that the positive population is somewhere on the high end of the measurement range and the negative population is on the low end. This parameter allows to disregard populations with mean values in the extreme quantiles of the data range. It’s value should be in the range $[0, 1]$.
- **absolute**: Logical controlling whether to classify a population (positive or negative) relative to the theoretical measurement range of the instrument or the actual range of the data. This can be set to `TRUE` if the alignment of the measurement range is not optimal and the bulk of the data is on one end of the theoretical range.
- **filterId**: Character, the name assigned to the resulting filter.
- **positive**: Create a range gate that includes the positive (`TRUE`) or the negative (`FALSE`) population.
- **refLine**: Either `NULL` or a numeric of length 1. If `NULL`, this parameter is ignored. When it is set to a numeric, the minor sub-population (if any) below this reference line will be ignored while determining the separator between positive and negative.
- **simple**: Logical scalar indicating whether to use a simple peak finding version of density1d algorithm.
- **...**: Further arguments.

Details

The algorithm first tries to identify high density regions in the data. If the input is a `flowSet`, density regions will be computed on the collapsed data, hence it should have been normalized before (see `warpSet` for one possible normalization technique). The high density regions are then classified as positive and negative populations, based on their mean value in the theoretical (or absolute if argument `absolute=TRUE`) measurement range. In case there are only two high-density regions the lower one is usually classified as the negative populations, however the heuristics in the algorithm will force the classification towards a positive population if the mean value is already very high. The `absolute` and `borderQuant` arguments can be used to control this behaviour. The split point
between populations will be drawn at the value of minimum local density between the two populations, or, if the alpha argument is used, somewhere between the two populations where the value of alpha forces the point to be closer to the negative (0 - 0.5) or closer to the positive population (0.5 - 1).

If there is only a single high-density region, the algorithm will fall back to estimating the mode of the distribution (hubers) and a robust measure of it’s variance and, in combination with the sd argument, set the split point somewhere in the right or left tail, depending on the classification of the region.

For more than two populations, the algorithm will still classify each population into positive and negative and compute the split point between those clusters, similar to the two population case.

The rangeFilter class and constructor provide the means to treat rangeGate as regular flowCore filters.

Value

A range gate, more explicitly an object of class rectangleGate.

Methods

%in% signature(x = "flowFrame", table = "rangeFilter"): the work horse for doing the actual filtering. Internally, this simply calls the rangeGate function.

SimulateMixture

Random Generation from a t Mixture Model with Box-Cox Transformation

Description

This function can be used to generate a sample from a multivariate $t$ mixture model with Box-Cox transformation.

Usage

SimulateMixture(N, w, mu, sigma, nu = 4, lambda)

Arguments

- **N**: The number of observations.
- **w**: A vector of length $K$, containing the $K$ cluster proportions.
- **mu**: A matrix of size $K \times P$, where $K$ is the number of clusters and $P$ is the dimension, containing the $K$ mean vectors.
- **sigma**: An array of dimension $K \times P \times P$, containing the $K$ covariance matrices.
- **nu**: The degrees of freedom used for the $t$ distribution.
- **lambda**: The Box-Cox transformation parameter. If missing, the conventional $t$ distribution without transformation will be used.

Value

A matrix of size $N \times P$.

spillover-flowSet  
Compute a spillover matrix from a flowSet

Description
Spillover information for a particular experiment is often obtained by running several tubes of beads or cells stained with a single color that can then be used to determine a spillover matrix for use with `compensate`.

When matching stain channels in x with the compensation controls, we provide a few options. If `ordered`, we assume the ordering of the channels in the flowSet object is the same as the ordering of the compensation-control samples. If `regexpr`, we use a regular expression to match the channel names with the names of each of the compensation control flowFrames (that is, `sampleNames(x)` which will typically be the filenames passed to `read.FCS`). By default, we must "guess" based on the largest statistic for the compensation control (i.e., the row).

Additionally, matching of channels to compensation control files can be accomplished using the `spillover_match` method, which allows the matches to be specified using a csv file. The `flowSet` returned by the `spillover_match` method should then be used as the x argument to `spillover` with `prematched = TRUE`.

Usage
## S4 method for signature 'flowSet'
spillover(
  x,
  unstained = NULL,
  fsc = "FSC-A",
  ssc = "SSC-A",
  patt = NULL,
  method = "median",
  stain_match = c("intensity", "ordered", "regexpr"),
  useNormFilt = FALSE,
  prematched = FALSE,
spillover-flowSet

```r
exact_match = FALSE
```

Arguments

- **x**: A flowSet of compensation beads or cells
- **unstained**: The name or index of the unstained negative control
- **fsc**: The name or index of the forward scatter parameter
- **ssc**: The name or index of the side scatter parameter
- **patt**: An optional regular expression defining which parameters should be considered
- **method**: The statistic to use for calculation. Traditionally, this has been the median so it is the default. The mean is sometimes more stable.
- **stain_match**: Determines how the stain channels are matched with the compensation controls. See details.
- **useNormFilt**: logical Indicating whether to apply a norm2Filter first before computing the spillover
- **prematched**: a convenience argument specifying if the channels have already been matched by spillover_match. This will override the values of unstained and stain_match with unstained = "unstained" and stain_match = "regexpr".
- **exact_match**: a logical specifying if we should use "regex" or "exact match" to match column names. The spillover_ng will pass exact_match and "regexpr" method will be over-ridden.

Details

The algorithm used is fairly simple. First, using the scatter parameters, we restrict ourselves to the most closely clustered population to reduce the amount of debris. The selected statistic is then calculated on all appropriate parameters and the unstained values swept out of the matrix. Every sample is then normalized to [0,1] with respect to the maximum value of the sample, giving the spillover in terms of a proportion of the primary channel intensity.

Value

A matrix for each of the parameters

Author(s)

B. Ellis, J. Wagner

compensate, spillover_match
Spillover information for a particular experiment is often obtained by running several tubes of beads or cells stained with a single color that can then be used to determine a spillover matrix for use with `compensate`.

This method facilitates construction of a `flowSet` of compensation control `flowFrames` using a simple file linking filenames to channels. This resulting `flowSet` can then be used with `spillover` using the option `prematched = TRUE`.

Matching stain channels to compensation controls is done via a csv file (`matchfile`) with columns 'filename' and 'channel'. The 'channel' entries should exactly match the channel names in the FCS files. The 'filename' should be the FCS file name of each compensation control which should also be the corresponding sample name in the `flowSet`. There should also be one unstained control with the 'channel' entry of 'unstained'.

The method also allows for `x` to be missing if `path` is provided, pointing to a directory containing the control FCS files.

Usage

```r
## S4 method for signature 'flowSet'
spillover_match(x, fsc = "FSC-A", ssc = "SSC-A", 
               matchfile = NULL, path)

## S4 method for signature 'missing'
spillover_match(x, fsc = "FSC-A", ssc = "SSC-A", matchfile, path)
```

Arguments

- `x` A `flowSet` of compensation beads or cells
- `fsc` The name or index of the forward scatter parameter
- `ssc` The name or index of the side scatter parameter
- `matchfile` The name or path of the csv file holding the compensation control file to channel matching information.
- `path` The name or path of the directory containing the control FCS files to be matched to channels by `matchfile`.
Value

A flowSet with the sample names of its flowFrames corresponding to the channels specified by the matchfile.

spillover_ng-flowSet  Compute a spillover matrix from a flowSet, simplified API

Description

Spillover information for a particular experiment is often obtained by running several tubes of beads or cells stained with a single color that can then be used to determine a spillover matrix for use with 

compensate.

Matching stain channels to compensation controls is done via a matching csv file (at the path given by matchfile) with columns 'filename' and 'channel'. The 'channel' entries should exactly match the channel names in the FCS files. The 'filename' should be the FCS file name of each compensation control which should also be the corresponding sample name in the flowSet. There should also be one unstained control with the 'channel' entry of 'unstained'.

The method also allows for x to be missing if path is provided, pointing to a directory containing the control FCS files.

By default, pregating is always done on the channels using this API, and the mode of the channel is used to compute the spillover matrix. FSC and SSC channels can be provided to allow a pregating on (approximately) a population in the FSC and SSC dimensions. Also by default, a norm2Filter is applied before computing the spillover. These defaults can be overridden using the pregate, method, and useNormFilt arguments.

Usage

```r
## S4 method for signature 'flowSet'
spillover_ng(x, fsc = "FSC-A", ssc = "SSC-A",
            plot = FALSE, matchfile, path,
            useNormFilt = TRUE, patt = NULL, pregate = TRUE, method = "mode", ...)

## S4 method for signature 'missing'
spillover_ng(x, fsc = "FSC-A", ssc = "SSC-A",
            plot = FALSE, matchfile, path,
            useNormFilt = TRUE, patt = NULL, pregate = TRUE, method = "mode", ...)
```
## S4 method for signature 'missing'
spillover_ng(
  x,
  fsc = "FSC-A",
  ssc = "SSC-A",
  plot = FALSE,
  matchfile,
  path,
  useNormFilt = TRUE,
  patt = NULL,
  pregate = TRUE,
  method = "mode",
  ...
)

Arguments

- **x**: A flowSet of compensation beads or cells
- **fsc**: The name or index of the forward scatter parameter
- **ssc**: The name or index of the side scatter parameter
- **plot**: logical. Plots the kernel density for each channel when pregating. Displays the gate used. If pregate is set to FALSE, this argument is ignored.
- **matchfile**: Name of the csv file holding the compensation control file to channel matching information.
- **path**: A path to a directory containing the control files, to be used if x is not provided.
- **useNormFilt**: logical. Indicating whether to apply a `norm2Filter` first before computing the spillover.
- **patt**: An optional regular expression defining which parameters should be considered
- **pregate**: logical. Indicating whether to pregate using `link{rangeGate}` before computing the spillover.
- **method**: The statistic to use for calculation. Traditionally, this has been the median so it is the default. The mean is sometimes more stable.
- **...**: Additional arguments passed to `rangeGate`.

Details

The algorithm used is fairly simple. First, using the scatter parameters, we restrict ourselves to the most closely clustered population to reduce the amount of debris. The selected statistic is then calculated on all appropriate parameters and the unstained values swept out of the matrix. Every sample is then normalized to [0,1] with respect to the maximum value of the sample, giving the spillover in terms of a proportion of the primary channel intensity.

Value

A matrix for each of the parameters
Author(s)
B. Ellis

warpSet
Normalization based on landmark registration

Description
This function will perform a normalization of flow cytometry data based on warping functions computed on high-density region landmarks for individual flow channels.

Usage
warpSet(x, ...)

## S3 method for class 'cytoset'
warpSet(
x, 
stains, 
grouping = NULL, 
subsample = NULL, 
peakNr = NULL, 
clipRange = 0.01, 
nbreaks = 11, 
fres, 
bwFac = 2, 
warpFuns = FALSE, 
target = NULL, 
chunksize = 10, 
... 
)

Arguments

x A flowSet.

... Further arguments that are passed on to landmarkreg.

stains A character vector of flow parameters in x to be normalized.
warpSet

grouping A character indicating one of the phenotypic variables in the phenoData slot of x used as a grouping factor. The within-group and between-group variance is computed and a warning is issued in case the latter is bigger than the former, indicating the likely removal of signal by the normalization procedure. landmarkreg.

subsample Numeric. Reduce the number of events in each flowSet by sub sampling for all density estimation steps and the calculation of the warping functions. This can increase computation time for large data sets, however it might reduce the accuracy of the density estimates. To be used with care.

peakNr Numeric scalar. Force a fixed number of peaks to use for the normalization.

clipRange Only use peaks within a clipped data range. Essentially, the number indicates the percent of clipping on both sides of the data range, e.g. \( \min(x) - 0.01 \times \text{diff(range}(x)) \).

nbreaks The number of spline sections used to approximate the data. Higher values produce more accurate results, however this comes with the cost of increased computing times. For most data, the default setting is good enough.

fres A named list of filterResultList objects. This can be used to speed up the process since the curv1Filter step can take quite some time.

bwFac Numeric of length 1 used to set the bandwidth factor by curv1Filter for smoothing of the density estimate.

warpFuns Logical indicating whether to return the normalized flowSet or a list of warping functions.

target Character vector specifying the target sample to which other samples in the flowSet should be normalized. If NULL, then the mean of the peaks is used.

chunksize an integer. For a memory-efficient implementation of normalization, chunksize can be set to perform normalization on chunks of the data of size chunksize

Details

Normalization is achieved by first identifying high-density regions (landmarks) for each flowFrame in the flowSet for a single channel and subsequently by computing warping functions for each flowFrame that best align these landmarks. This is based on the algorithm implemented in the landmarkreg function in the fda package. An intermediate step classifies the high-density regions, see landmarkMatrix for details.

Please note that this normalization is on a channel-by-channel basis. Multiple channels are normalized in a loop.

Value

The normalized flowSet if warpFuns is FALSE, otherwise a list of warping functions. Additional information is attached as the warping attribute to the flowSet in form of a list.

Note

We currently use a patched fda version.
