

Package ‘gdsfmt’

March 16, 2018

Type Package

Title R Interface to CoreArray Genomic Data Structure (GDS) Files

Version 1.14.1

Date 2017-12-16

Depends R (>= 2.15.0), methods

Suggests parallel, digest, crayon, RUnit, knitr, BiocGenerics

Author Xiuwen Zheng [aut, cre], Stephanie Gogarten [ctb], Jean-loup Gailly and Mark Adler [ctb] (for the included zlib sources), Yann Collet [ctb] (for the included LZ4 sources), xz contributors (for the included liblzma sources)

Maintainer Xiuwen Zheng <zhengx@u.washington.edu>

Description This package provides a high-level R interface to CoreArray Genomic Data Structure (GDS) data files, which are portable across platforms with hierarchical structure to store multiple scalable array-oriented data sets with metadata information. It is suited for large-scale datasets, especially for data which are much larger than the available random-access memory. The gdsfmt package offers the efficient operations specifically designed for integers of less than 8 bits, since a diploid genotype, like single-nucleotide polymorphism (SNP), usually occupies fewer bits than a byte. Data compression and decompression are available with relatively efficient random access. It is also allowed to read a GDS file in parallel with multiple R processes supported by the package parallel.

`gdsfmt-package`*R Interface to CoreArray Genomic Data Structure (GDS) files*

Description

This package provides a high-level R interface to CoreArray Genomic Data Structure (GDS) data files, which are portable across platforms and include hierarchical structure to store multiple scalable array-oriented data sets with metadata information. It is suited for large-scale datasets, especially for data which are much larger than the available random-access memory. The `gdsfmt` package offers the efficient operations specifically designed for integers with less than 8 bits, since a single genetic/genomic variant, such like single-nucleotide polymorphism, usually occupies fewer bits than a byte. It is also allowed to read a GDS file in parallel with multiple R processes supported by the parallel package.

Details

Package: `gdsfmt`
Type: R/Bioconductor Package
License: LGPL version 3

R interface of CoreArray GDS is based on the CoreArray project initiated and developed from 2007 (<http://corearray.sourceforge.net>). The CoreArray project is to develop portable, scalable, bioinformatic data visualization and storage technologies.

R is the most popular statistical environment, but one not necessarily optimized for high performance or parallel computing which ease the burden of large-scale calculations. To support efficient data management in parallel for numerical genomic data, we developed the Genomic Data Structure (GDS) file format. `gdsfmt` provides fundamental functions to support accessing data in parallel, and allows future R packages to call these functions.

Webpage: <http://corearray.sourceforge.net>, <http://github.com/zhengxwen/gdsfmt>

Copyright notice: The package includes the sources of CoreArray C++ library written by Xiuwen Zheng (LGPL-3), `zlib` written by Jean-loup Gailly and Mark Adler (`zlib` license), and LZ4 written by Yann Collet (simplified BSD).

Author(s)

Xiuwen Zheng <zhengx@u.washington.edu>

Examples

```
# create a GDS file
f <- createfn.gds("test.gds")
```

```

L <- -2500:2499

# common types
add.gdsn(f, "label", NULL)
add.gdsn(f, "int", val=1:10000, compress="ZIP", closezip=TRUE)
add.gdsn(f, "int.matrix", val=matrix(L, nrow=100, ncol=50))
add.gdsn(f, "mat", val=matrix(1:(10*6), nrow=10))
add.gdsn(f, "double", val=seq(1, 1000, 0.4))
add.gdsn(f, "character", val=c("int", "double", "logical", "factor"))
add.gdsn(f, "logical", val=rep(c(TRUE, FALSE, NA), 50))
add.gdsn(f, "factor", val=as.factor(c(letters, NA, "AA", "CC")))
add.gdsn(f, "NA", val=rep(NA, 10))
add.gdsn(f, "NaN", val=c(rep(NaN, 20), 1:20))
add.gdsn(f, "bit2-matrix", val=matrix(L[1:5000], nrow=50, ncol=100),
  storage="bit2")
# list and data.frame
add.gdsn(f, "list", val=list(X=1:10, Y=seq(1, 10, 0.25)))
add.gdsn(f, "data.frame", val=data.frame(X=1:19, Y=seq(1, 10, 0.5)))

# save a .RData object
obj <- list(X=1:10, Y=seq(1, 10, 0.1))
save(obj, file="tmp.RData")
addfile.gdsn(f, "tmp.RData", filename="tmp.RData")

f

read.gdsn(index.gdsn(f, "list"))
read.gdsn(index.gdsn(f, "list/Y"))
read.gdsn(index.gdsn(f, "data.frame"))
read.gdsn(index.gdsn(f, "mat"))

# Apply functions over columns of matrix
tmp <- apply.gdsn(index.gdsn(f, "mat"), margin=2, FUN=function(x) print(x))
tmp <- apply.gdsn(index.gdsn(f, "mat"), margin=2,
  selection = list(rep(c(TRUE, FALSE), 5), rep(c(TRUE, FALSE), 3)),
  FUN=function(x) print(x))

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)

```

add.gdsn

Add a new GDS node

Description

Add a new GDS node to the GDS file.

Usage

```

add.gdsn(node, name, val=NULL, storage=storage.mode(val), valdim=NULL,
  compress=c("", "ZIP", "ZIP_RA", "LZMA", "LZMA_RA", "LZ4", "LZ4_RA"),
  closezip=FALSE, check=TRUE, replace=FALSE, visible=TRUE, ...)

```

Arguments

node	an object of class <code>gdsn.class</code> or <code>gds.class</code> : <code>"gdsn.class"</code> – the node of hierarchical structure; <code>"gds.class"</code> – the root of hierarchical structure
name	the variable name; if it is not specified, a temporary name is assigned
val	the R value can be integers, real numbers, characters, factor, logical or raw variable, list and <code>data.frame</code>
storage	to specify data type (not case-sensitive), signed integer: <code>"int8"</code> , <code>"int16"</code> , <code>"int24"</code> , <code>"int32"</code> , <code>"int64"</code> , <code>"sbit2"</code> , <code>"sbit3"</code> , ..., <code>"sbit16"</code> , <code>"sbit24"</code> , <code>"sbit32"</code> , <code>"sbit64"</code> , <code>"v1_int"</code> (encoding variable-length signed integer); unsigned integer: <code>"uint8"</code> , <code>"uint16"</code> , <code>"uint24"</code> , <code>"uint32"</code> , <code>"uint64"</code> , <code>"bit1"</code> , <code>"bit2"</code> , <code>"bit3"</code> , ..., <code>"bit16"</code> , <code>"bit24"</code> , <code>"bit32"</code> , <code>"bit64"</code> , <code>"v1_uint"</code> (encoding variable-length unsigned integer); floating-point number (<code>"float32"</code> , <code>"float64"</code>); packed real number (<code>"packedreal8"</code> , <code>"packedreal16"</code> , <code>"packedreal24"</code> , <code>"packedreal32"</code> : pack a floating-point number to a 8/16/24/32-bit integer with two attributes <code>"offset"</code> and <code>"scale"</code> , representing <code>"int*scale + offset"</code>); string (variable-length: <code>"string"</code> , <code>"string16"</code> , <code>"string32"</code> ; C [null-terminated] string: <code>"cstring"</code> , <code>"cstring16"</code> , <code>"cstring32"</code> ; fixed-length: <code>"fstring"</code> , <code>"fstring16"</code> , <code>"fstring32"</code>). Or <code>"char"</code> (<code>"=int8"</code>), <code>"int"/"integer"</code> (<code>"=int32"</code>), <code>"float"</code> (<code>"=float32"</code>), <code>"double"</code> (<code>"=float64"</code>), <code>"character"</code> (<code>"=string"</code>), <code>"logical"</code> , <code>"list"</code> , <code>"factor"</code> , <code>"folder"</code> ; Or a <code>gdsn.class</code> object, the storage mode is set to be the same as the object specified by storage.
valdim	the dimension attribute for the array to be created, which is a vector of length one or more giving the maximal indices in each dimension
compress	the compression method can be <code>""</code> (no compression), <code>"ZIP"</code> , <code>"ZIP.fast"</code> , <code>"ZIP.def"</code> , <code>"ZIP.max"</code> or <code>"ZIP.none"</code> (original zlib); <code>"ZIP_RA"</code> , <code>"ZIP_RA.fast"</code> , <code>"ZIP_RA.def"</code> , <code>"ZIP_RA.max"</code> or <code>"ZIP_RA.none"</code> (zlib with efficient random access); <code>"LZ4"</code> , <code>"LZ4.none"</code> , <code>"LZ4.fast"</code> , <code>"LZ4.hc"</code> or <code>"LZ4.max"</code> (LZ4 compression/decompression library); <code>"LZ4_RA"</code> , <code>"LZ4_RA.none"</code> , <code>"LZ4_RA.fast"</code> , <code>"LZ4_RA.hc"</code> or <code>"LZ4_RA.max"</code> (with efficient random access); <code>"LZMA"</code> , <code>"LZMA.fast"</code> , <code>"LZMA.def"</code> , <code>"LZMA.max"</code> , <code>"LZMA_RA"</code> , <code>"LZMA_RA.fast"</code> , <code>"LZMA_RA.def"</code> , <code>"LZMA_RA.max"</code> (lzma compression/decompression algorithm). See details
closezip	if a compression method is specified, get into read mode after compression
check	if TRUE, a warning will be given when <code>val</code> is character and there are missing values in <code>val</code> . GDS format does not support missing characters NA, and any NA will be converted to a blank string <code>""</code>
replace	if TRUE, replace the existing variable silently if possible
visible	FALSE – invisible/hidden, except <code>print(, all=TRUE)</code>
...	additional parameters for specific storage, see details

Details

`val`: if `val` is `list` or `data.frame`, the child node(s) will be added corresponding to objects in `list` or `data.frame`. If calling `add.gdsn(node, name, val=NULL)`, then a label will be added which does not have any other data except the name and attributes. If `val` is raw-type, it is interpreted as 8-bit signed integer.

`storage`: the default value is `storage.mode(val)`, `"int"` denotes signed integer, `"uint"` denotes unsigned integer, 8, 16, 24, 32 and 64 denote the number of bits. `"bit1"` to `"bit32"` denote the packed data types for 1 to 32 bits which are packed on disk, and `"sbit2"` to `"sbit32"` denote the corresponding signed integers. `"float32"` denotes single-precision number, and `"float64"` denotes double-precision

number. "string" represents strings of 8-bit characters, "string16" represents strings of 16-bit characters following UTF16 industry standard, and "string32" represents a string of 32-bit characters following UTF32 industry standard. "folder" is to create a folder.

valdim: the values in data are taken to be those in the array with the leftmost subscript moving fastest. The last entry could be ZERO. If the total number of elements is zero, gdsfmt does not allocate storage space. NA is treated as 0.

compress: Z compression algorithm (<http://www.zlib.net/>) can be used to deflate the data stored in the GDS file. "ZIP" option is equivalent to "ZIP.def". "ZIP.fast", "ZIP.def" and "ZIP.max" correspond to different compression levels.

To support efficient random access of Z stream, "ZIP_RA", "ZIP_RA.fast", "ZIP_RA.def" or "ZIP_RA.max" should be specified. "ZIP_RA" option is equivalent to "ZIP_RA.def:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K", "512K", "1M", "2M", "4M" and "8M" are allowed, like "ZIP_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

LZ4 fast lossless compression algorithm is allowed when compress="LZ4" (<http://code.google.com/p/lz4/>). Three compression levels can be specified, "LZ4.fast" (LZ4 fast mode), "LZ4.hc" (LZ4 high compression mode), "LZ4.max" (maximize the compression ratio). The block size can be specified by following colon, and "64K", "256K", "1M" and "4M" are allowed according to LZ4 frame format. "LZ4" is equivalent to "LZ4.hc:256K".

To support efficient random access of LZ4 stream, "LZ4_RA", "LZ4_RA.fast", "LZ4_RA.hc" or "ZIP_RA.max" should be specified. "LZ4_RA" option is equivalent to "LZ4_RA.hc:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K", "512K", "1M", "2M", "4M" and "8M" are allowed, like "LZ4_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

LZMA compression algorithm (<http://tukaani.org/xz/>) is available since gdsfmt_v1.7.18, which has a higher compression ratio than ZIP algorithm. "LZMA", "LZMA.fast", "LZMA.def" and "LZMA.max" available. To support efficient random access of LZMA stream, "LZMA_RA", "LZMA_RA.fast", "LZMA_RA.def" and "LZMA_RA.max" can be used. The block size can be specified by following colon. "LZMA_RA" is equivalent to "LZMA_RA.def:256K".

To finish compressing, you should call [readmode.gdsn](#) to close the writing mode.

closezip: if compression option is specified, then enter a read mode after deflating the data. see [readmode.gdsn](#).

...: if storage = "fstring", "fstring16" or "fstring32", users can set the max length of string in advance by maxlen=. If storage = "packedreal8", "packedreal16" or "packedreal32", users can define offset and scale to represent real numbers by "value*scale + offset" where "value" is a 8/16/32-bit integer. By default, offset=0, scale=0.01 for "packedreal8", scale=0.0001 for "packedreal16", scale=0.00001 for "packedreal24", scale=0.000001 for "packedreal32".

Value

An object of class [gdsn.class](#) of the new node.

closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

addfile.gdsn

Add a GDS node with a file

Description

Add a file to a GDS file as a node.

Usage

```
addfile.gdsn(node, name, filename,
             compress=c("ZIP", "ZIP_RA", "LZMA", "LZMA_RA", "LZ4", "LZ4_RA"),
             replace=FALSE, visible=TRUE)
```

Arguments

node	an object of class <code>gdsn.class</code> or <code>gds.class</code>
name	the variable name; if it is not specified, a temporary name is assigned
filename	the file name of input stream.
compress	the compression method can be "" (no compression), "ZIP", "ZIP.fast", "ZIP.default", "ZIP.max" or "ZIP.none" (original zlib); "ZIP_RA", "ZIP_RA.fast", "ZIP_RA.default", "ZIP_RA.max" or "ZIP_RA.none" (zlib with efficient random access); "LZ4", "LZ4.none", "LZ4.fast", "LZ4.hc" or "LZ4.max"; "LZ4_RA", "LZ4_RA.none", "LZ4_RA.fast", "LZ4_RA.hc" or "LZ4_RA.max" (with efficient random access). See details
replace	if TRUE, replace the existing variable silently if possible
visible	FALSE – invisible/hidden, except <code>print(, all=TRUE)</code>

Details

compress: Z compression algorithm (<http://www.zlib.net/>) can be used to deflate the data stored in the GDS file. "ZIP" option is equivalent to "ZIP.default". "ZIP.fast", "ZIP.default" and "ZIP.max" correspond to different compression levels.

To support efficient random access of Z stream, "ZIP_RA", "ZIP_RA.fast", "ZIP_RA.default", "ZIP_RA.max" or "ZIP_RA.none" should be specified. "ZIP_RA" option is equivalent to "ZIP_RA.default:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K",

"512K", "1M", "2M", "4M" and "8M" are allowed, like "ZIP_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

LZ4 fast lossless compression algorithm is allowed when compress="LZ4" (<http://code.google.com/p/lz4/>). Three compression levels can be specified, "LZ4.fast" (LZ4 fast mode), "LZ4.hc" (LZ4 high compression mode), "LZ4.max" (maximize the compression ratio). The block size can be specified by following colon, and "64K", "256K", "1M" and "4M" are allowed according to LZ4 frame format. "LZ4" is equivalent to "LZ4.hc:256K".

To support efficient random access of LZ4 stream, "LZ4_RA", "LZ4_RA.fast", "LZ4_RA.hc", "ZIP_RA.max" or "LZ4_RA.none" should be specified. "LZ4_RA" option is equivalent to "LZ4_RA.hc:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K", "512K", "1M", "2M", "4M" and "8M" are allowed, like "LZ4_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

Value

An object of class `gdsn.class`.

`getfile.gdsn`, `add.gdsn`

Examples

```
# save a .RData object
obj <- list(X=1:10, Y=seq(1, 10, 0.1))
save(obj, file="tmp.RData")

# create a GDS file
f <- createfn.gds("test.gds")

add.gdsn(f, "double", val=seq(1, 1000, 0.4))
addfile.gdsn(f, "tmp.RData", "tmp.RData")

# open the GDS file
closefn.gds(f)

# open the existing file
(f <- openfn.gds("test.gds"))

getfile.gdsn(index.gdsn(f, "tmp.RData"), "tmp1.RData")
(obj <- get(load("tmp1.RData"))))

# open the GDS file
closefn.gds(f)
```

```
# delete the temporary files
unlink(c("test.gds", "tmp.RData", "tmp1.RData"), force=TRUE)
```

addfolder.gdsn *Add a folder to the GDS node*

Description

Add a directory or a virtual folder to the GDS node.

Usage

```
addfolder.gdsn(node, name, type=c("directory", "virtual"), gds.fn="",
               replace=FALSE, visible=TRUE)
```

Arguments

node	an object of class <code>gdsn.class</code> or <code>gds.class</code>
name	the variable name; if it is not specified, a temporary name is assigned
type	"directory" (default) – create a directory of GDS node; "virtual" – create a virtual folder linking another GDS file by mapping all of the content to this virtual folder
gds.fn	the name of another GDS file; it is applicable only if type="virtual"
replace	if TRUE, replace the existing variable silently if possible
visible	FALSE – invisible/hidden, except print(, all=TRUE)

Value

An object of class `gdsn.class`.

f1

# open the GDS file
closefn.gds(f1)

#####

# create the second GDS file
f2 <- createfn.gds("test2.gds")

add.gdsn(f2, "int", 101:200)

# link to the first file
addfolder.gdsn(f2, "virtual_folder", type="virtual", gds.fn="test1.gds")

f2

# open the GDS file
closefn.gds(f2)

#####

# open the second file (writable)
(f <- openfn.gds("test2.gds", FALSE))
# + [ ]
# |--+ int { Int32 100, 400 bytes }
# |--+ virtual_folder [ --> test1.gds ]
# | |--+ NULL
# | |--+ dir [ ]
# | |--+ int { Int32 100, 400 bytes }

read.gdsn(index.gdsn(f, "int"))
read.gdsn(index.gdsn(f, "virtual_folder/int"))
add.gdsn(index.gdsn(f, "virtual_folder/dir"), "nm", 1:10)

f

# open the GDS file
closefn.gds(f)

#####
# open 'test1.gds', there is a new variable "dir/nm"

(f <- openfn.gds("test1.gds"))
closefn.gds(f)

```

```
#####
# remove 'test1.gds'

file.remove("test1.gds")

## Not run:
(f <- openfn.gds("test2.gds"))
# + [ ]
# |--+ int { Int32 100, 400 bytes }
# |--+ virtual_folder [ -X- test1.gds ]

closefn.gds(f)
## End(Not run)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

append.gdsn

Append data to a specified variable

Description

Append new data to the data field of a GDS node.

Usage

```
append.gdsn(node, val, check=TRUE)
```

Arguments

node	an object of class <code>gdsn.class</code>
val	R primitive data, like integer; or an object of class <code>gdsn.class</code>
check	whether a warning is given, when appended data can not match the capability of data field; if val is character-type, a warning will be shown if there is any NA in val

Details

`storage.mode(val)` should be "integer", "double", "character" or "logical". GDS format does not support missing characters NA, and any NA will be converted to a blank string "".

Value

None.

f

# no warning here, and add a new column
append.gdsn(n, -51:-100)
f

# you should call "readmode.gdsn" before reading, since compress="ZIP"
readmode.gdsn(n)

# check the last column
read.gdsn(n, start=c(1, 102), count=c(-1, 1))

# characters
n <- add.gdsn(f, "string", val=as.character(1:100))
append.gdsn(n, as.character(rep(NA, 25)))

read.gdsn(n)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

apply.gdsn

Apply functions over margins

Description

Return a vector or list of values obtained by applying a function to margins of a GDS matrix or array.

Usage

```
apply.gdsn(node, margin, FUN, selection=NULL,
  as.is=c("list", "none", "integer", "double", "character", "logical",
  "raw", "gdsn"), var.index=c("none", "relative", "absolute"),
  target.node=NULL, .useraw=FALSE, .value=NULL, .substitute=NULL, ...)
```

Arguments

node	an object of class <code>gdsn.class</code> , or a list of objects of class <code>gdsn.class</code>
margin	an integer giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns
FUN	the function to be applied
selection	a list or NULL; if a list, it is a list of logical vectors according to dimensions indicating selection; if NULL, uses all data
as.is	returned value: a list, an integer vector, etc; "gdsn" – the returned value from the user-defined function will be appended to target.node.
var.index	if "none", call FUN(x, ...) without an index; if "relative" or "absolute", add an argument to the user-defined function FUN like FUN(index, x, ...) where index in the function is an index starting from 1: "relative" for indexing in the selection defined by selection, "absolute" for indexing with respect to all data
target.node	NULL, an object of class <code>gdsn.class</code> or a list of <code>gdsn.class</code> : output to the target GDS node(s) when as.is="gdsn". See details
.useraw	use R RAW storage mode if integers can be stored in a byte, to reduce memory usage
.value	a vector of values to be replaced in the original data array, or NULL for nothing
.substitute	a vector of values after replacing, or NULL for nothing; length(.substitute) should be one or length(.value); if length(.substitute) = length(.value), it is a mapping from .value to .substitute
...	optional arguments to FUN

Details

The algorithm is optimized by blocking the computations to exploit the high-speed memory instead of disk.

When as.is="gdsn" and there are more than one `gdsn.class` object in target.node, the user-defined function should return a list with elements corresponding to target.node, or NULL indicating no appending.

Value

A vector or list of values.

assign.gdsn

*Assign/append data to a GDS node***Description**

Assign data to a GDS node, or append data to a GDS node

Usage

```
assign.gdsn(node, src.node=NULL, resize=TRUE, seldim=NULL, append=FALSE,
            .value=NULL, .substitute=NULL)
```

Arguments

node	an object of class <code>gdsn.class</code> , a target GDS node
src.node	an object of class <code>gdsn.class</code> , a source GDS node
resize	whether call <code>setdim.gdsn</code> to reset the dimension(s)
seldim	the selection of <code>src.obj</code> with numeric or logical indicators, or NULL for all data
append	if TRUE, append data by calling <code>append.gdsn</code> ; otherwise, replace the old one
.value	a vector of values to be replaced in the original data array, or NULL for nothing
.substitute	a vector of values after replacing, or NULL for nothing; <code>length(.substitute)</code> should be one or <code>length(.value)</code> ; if <code>length(.substitute) = length(.value)</code> , it is a mapping from <code>.value</code> to <code>.substitute</code>

Value

None.

```

cache.gdsn

Caching variable data

Description

Caching the data associated with a GDS variable

Usage

```
cache.gdsn(node)
```

Arguments

node an object of class `gdsn.class`, a GDS node

Details

If random access of array-based data is required, it is possible to speed up the access time by caching data in memory. This function tries to force the operating system to cache the data associated with the GDS node, however how to cache data depends on the configuration of operating system, including system memory and caching strategy. Note that this function does not explicitly allocate memory for the data.

If the data has been compressed, caching strategy almost has no effect on random access, since the data has to be decompressed serially.

Value

None.

# delete the temporary file
unlink("test.gds", force=TRUE)
```

closefn.gds

Close a GDS file

Description

Close a CoreArray Genomic Data Structure (GDS) file.

Usage

```
closefn.gds(gdsfile)
```

Arguments

gdsfile an object of class `gds.class`, a GDS file

Details

For better performance, data in a GDS file are usually cached in memory. Keep in mind that the new file may not actually be written to disk, until `closefn.gds` or `sync.gds` is called. Anyway, when R shuts down, all GDS files created or opened would be automatically closed.

Value

None.

# delete the temporary file
unlink("test.gds", force=TRUE)
```

clusterApply.gdsn *Apply functions over matrix margins in parallel*

Description

Return a vector or list of values obtained by applying a function to margins of a GDS matrix in parallel.

Usage

```
clusterApply.gdsn(cl, gds.fn, node.name, margin, FUN, selection=NULL,
  as.is=c("list", "none", "integer", "double", "character", "logical", "raw"),
  var.index=c("none", "relative", "absolute"), .useraw=FALSE,
  .value=NULL, .substitute=NULL, ...)
```

Arguments

<code>cl</code>	a cluster object, created by this package or by the package parallel
<code>gds.fn</code>	the file name of a GDS file
<code>node.name</code>	a character vector indicating GDS node path
<code>margin</code>	an integer giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns
<code>FUN</code>	the function to be applied
<code>selection</code>	a list or NULL; if a list, it is a list of logical vectors according to dimensions indicating selection; if NULL, uses all data
<code>as.is</code>	returned value: a list, an integer vector, etc
<code>var.index</code>	if "none", call FUN(x, ...) without an index; if "relative" or "absolute", add an argument to the user-defined function FUN like FUN(index, x, ...) where index in the function is an index starting from 1: "relative" for indexing in the selection defined by selection, "absolute" for indexing with respect to all data
<code>.useraw</code>	use R RAW storage mode if integers can be stored in a byte, to reduce memory usage
<code>.value</code>	a vector of values to be replaced in the original data array, or NULL for nothing
<code>.substitute</code>	a vector of values after replacing, or NULL for nothing; length(.substitute) should be one or length(.value); if length(.substitute) = length(.value), it is a mapping from .value to .substitute
<code>...</code>	optional arguments to FUN

Details

The algorithm of applying is optimized by blocking the computations to exploit the high-speed memory instead of disk.

Value

A vector or list of values.

cnt.gdsn

Return the number of child nodes

Description

Return the number of child nodes for a GDS node.

Usage

```
cnt.gdsn(node, include.hidden=FALSE)
```

Arguments

node an object of class `gdsn.class`, a GDS node
include.hidden whether including hidden variables or folders

Value

If node is a folder, return the numbers of variables in the folder including child folders. Otherwise, return 0.

compression.gdsn

Modify compression mode

Description

Modify the compression mode of data field in the GDS node.

Usage

```
compression.gdsn(node,
  compress=c("", "ZIP", "ZIP_RA", "LZMA", "LZMA_RA", "LZ4", "LZ4_RA"))
```

Arguments

node an object of class `gdsn.class`, a GDS node

compress the compression method can be "" (no compression), "ZIP", "ZIP.fast", "ZIP.def", "ZIP.max" or "ZIP.none" (original zlib); "ZIP_RA", "ZIP_RA.fast", "ZIP_RA.def", "ZIP_RA.max" or "ZIP_RA.none" (zlib with efficient random access); "LZ4", "LZ4.none", "LZ4.fast", "LZ4.hc" or "LZ4.max" (LZ4 compression/decompression library); "LZ4_RA", "LZ4_RA.none", "LZ4_RA.fast", "LZ4_RA.hc" or "LZ4_RA.max" (with efficient random access). "LZMA", "LZMA.fast", "LZMA.def", "LZMA.max", "LZMA_RA", "LZMA_RA.fast", "LZMA_RA.def", "LZMA_RA.max" (lzma compression/decompression algorithm). See details

Details

Z compression algorithm (<http://www.zlib.net/>) can be used to deflate the data stored in the GDS file. "ZIP" option is equivalent to "ZIP.def". "ZIP.fast", "ZIP.def" and "ZIP.max" correspond to different compression levels.

To support efficient random access of Z stream, "ZIP_RA", "ZIP_RA.fast", "ZIP_RA.def" or "ZIP_RA.max" should be specified. "ZIP_RA" option is equivalent to "ZIP_RA.def:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K", "512K", "1M", "2M", "4M" and "8M" are allowed, like "ZIP_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

LZ4 fast lossless compression algorithm is allowed when compress="LZ4" (<http://code.google.com/p/lz4/>). Three compression levels can be specified, "LZ4.fast" (LZ4 fast mode), "LZ4.hc" (LZ4 high compression mode), "LZ4.max" (maximize the compression ratio). The block size can be specified by following colon, and "64K", "256K", "1M" and "4M" are allowed according to LZ4 frame format. "LZ4" is equivalent to "LZ4.hc:256K".

To support efficient random access of LZ4 stream, "LZ4_RA", "LZ4_RA.fast", "LZ4_RA.hc" or "ZIP_RA.max" should be specified. "LZ4_RA" option is equivalent to "LZ4_RA.hc:256K". The block size can be specified by following colon, and "16K", "32K", "64K", "128K", "256K", "512K", "1M", "2M", "4M" and "8M" are allowed, like "LZ4_RA:64K". The compression algorithm tries to keep each independent compressed data block to be about of the specified block size, like 64K.

LZMA compression algorithm (<http://tukaani.org/xz/>) is available since gdsfmt_v1.7.18, which has a higher compression ratio than ZIP algorithm. "LZMA", "LZMA.fast", "LZMA.def" and "LZMA.max" available. To support efficient random access of LZMA stream, "LZMA_RA", "LZMA_RA.fast", "LZMA_RA.def" and "LZMA_RA.max" can be used. The block size can be specified by following colon. "LZMA_RA" is equivalent to "LZMA_RA.def:256K".

Value

Return node.

copyto.gdsn

Copy GDS nodes

Description

Copy GDS node(s) to a folder with a new name

Usage

```
copyto.gdsn(node, source, name=NULL)
```

Arguments

node	a folder of class <code>gdsn.class</code> or <code>gds.class</code>
source	an object of class <code>gdsn.class</code> or <code>gds.class</code>
name	a specified name; if NULL, it is determined by source

Value

f

copyto.gdsn(index.gdsn(f, "folder2"), index.gdsn(f, "folder1"))
f

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)

```

createfn.gds	<i>Create a GDS file</i>
--------------	--------------------------

Description

Create a new CoreArray Genomic Data Structure (GDS) file.

Usage

```
createfn.gds(filename, allow.duplicate=FALSE)
```

Arguments

filename	the file name of a new GDS file to be created
allow.duplicate	if TRUE, it is allowed to open a GDS file with read-only mode when it has been opened in the same R session

Details

Keep in mind that the new file may not actually be written to disk until [closefn.gds](#) or [sync.gds](#) is called.

Value

Return an object of class `gds.class`:

filename	the file name to be created
id	internal file id
root	an object of class <code>gdsn.class</code> , the root of hierachical structure
readonly	whether it is read-only or not

f

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

delete.attr.gdsn	<i>Delete attribute(s)</i>
------------------	----------------------------

Description

Remove the attribute(s) of a GDS node.

Usage

```
delete.attr.gdsn(node, name)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
name	the name(s) of an attribute

Value

None.

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

delete.gdsn

Delete a GDS node

Description

Delete a specified GDS node.

Usage

```
delete.gdsn(node, force=FALSE)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
force	if FALSE, it is not allowed to delete a non-empty folder

Value

None.

## Not run:
# delete "node", but an error occurs
delete.gdsn(node)

## End(Not run)

# delete "node"
delete.gdsn(node, TRUE)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

diagnosis.gds

Diagnose the GDS file

Description

Diagnose the GDS file and data information.

Usage

```
diagnosis.gds(gds)
```

Arguments

gds an object of class [gdsn.class](#) or [gds.class](#)

Value

A list with stream and chunk information.

If `gds` is a `"gds.class"` object (i.e., a GDS file), the function returns a list with components, like:

<code>stream</code>	summary of byte stream
<code>log</code>	event log records

If `gds` is a `"gdsn.class"` object, the function returns a list with components, like:

<code>head</code>	<code>total_size</code> , <code>chunk_offset</code> , <code>chunk_size</code>
<code>data</code>	<code>total_size</code> , <code>chunk_offset</code> , <code>chunk_size</code>
<code>...</code>

dat <- NULL
for (i in seq_len(length(adr$data$chunk_offset)))
{
  seek(f, adr$data$chunk_offset[i])
  dat <- c(dat, readBin(f, "raw", adr$data$chunk_size[i]))
}

identical(dat, rawval) # should be TRUE

close(f)

# delete the temporary file
unlink("test.gds", force=TRUE)

```

digest.gdsn

create hash function digests

Description

Create hash function digests for a GDS node.

Usage

```

digest.gdsn(node, algo=c("md5", "sha1", "sha256", "sha384", "sha512"),
  action=c("none", "Robject", "add", "add.Robj", "clear", "verify", "return"))

```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
algo	the algorithm to be used; currently available choices are "md5" (by default), "sha1", "sha256", "sha384", "sha512"
action	"none": nothing (by default); "Robject": convert to R object, i.e., raw, integer, double or character before applying hash digests; "add": add a barcode attribute; "add.Robj": add a barcode attribute generated from R object; "clear": remove all hash barcodes; "verify": verify data integrity if there is any hash code in the attributes, and stop if any fails; "return": compare the existing hash code in the attributes, and return FALSE if fails, NA if no hash code, and TRUE if the verification succeeds

Details

The R package `digest` should be installed to perform hash function digests.

Value

A character or NA_character_ when the hash algorithm is not available.

Author(s)

Xiuwen Zheng

References

```

gdsn.class *the class of GDS file*

Description

The class of a CoreArray Genomic Data Structure (GDS) file.

Value

There are three components:

filename	the file name to be created
id	internal file id, an integer
root	an object of class <code>gdsn.class</code> , the root of hierachical structure
readonly	whether it is read-only or not

f
get.attr.gdsn(node)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

getfile.gdsn

Output a file from a stream container

Description

Get a file from a GDS node of stream container.

Usage

```
getfile.gdsn(node, out.filename)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
out.filename	the file name of output stream

Value

None.

# delete the temporary file
unlink("test.gds", force=TRUE)

```

index.gdsn

Get the specified node

Description

Get a specified GDS node.

Usage

```
index.gdsn(node, path=NULL, index=NULL, silent=FALSE)
```

Arguments

node	an object of class <code>gdsn.class</code> (a GDS node), or <code>gds.class</code> (a GDS file)
path	the path specifying a GDS node with '/' as a separator
index	a numeric vector or characters, specifying the path; it is applicable if path=NULL
silent	if TRUE, return NULL if the specified node does not exist

Details

If index is a numeric vector, e.g., `c(1, 2)`, the result is the second child node of the first child of node. If index is a vector of characters, e.g., `c("list", "x")`, the result is the child node with name "x" of the "list" child node.

Value

An object of class `gdsn.class` for the specified node.

```

is.element.gdsn

whether the elements are in a set

Description

Determine whether the elements are in a specified set.

Usage

```
is.element.gdsn(node, set)
```

Arguments

node	an object of class <code>gdsn.class</code> (a GDS node)
set	the specified set of elements

Value

A logical vector or array.

# delete the temporary file
unlink("test.gds", force=TRUE)
```

lasterr.gds

Return the last error message

Description

Get the last error message and clear the error message(s) in the gdsfmt package.

Usage

```
lasterr.gds()
```

Value

Character.

Author(s)

Xiuwen Zheng

References

<http://github.com/zhengxwen/gdsfmt>

Examples

```
lasterr.gds()
```

ls.gdsn	<i>Return the names of child nodes</i>
---------	--

Description

Get a list of names for its child nodes.

Usage

```
ls.gdsn(node, include.hidden=FALSE)
```

Arguments

node an object of class `gdsn.class`, a GDS node
include.hidden whether including hidden variables or folders

Value

A vector of characters, or character(0) if node is not a folder.

Author(s)

Xiuwen Zheng

ls.gdsn(node)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

 moveto.gdsn

Relocate a GDS node

Description

Move a GDS node to a new place in the same file

Usage

```
moveto.gdsn(node, loc.node,
            relpos = c("after", "before", "replace", "replace+rename"))
```

Arguments

node	an object of class <code>gdsn.class</code> (a GDS node)
loc.node	an object of class <code>gdsn.class</code> (a GDS node), indicates the new location
relpos	"after": after loc.node, "before": before loc.node, "replace": replace loc.node (loc.node will be deleted); "replace+rename": replace loc.node (loc.node will be deleted and node has a new name as loc.node)

Value

None.

# delete the temporary file
unlink("test.gds", force=TRUE)

```

name.gdsn	<i>Return the variable name of a node</i>
-----------	---

Description

Get the variable name of a GDS node.

Usage

```
name.gdsn(node, fullname=FALSE)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
fullname	if FALSE, return the node name (by default); otherwise the name with a full path

Value

Characters.

node <- index.gdsn(f, "list/x")

name.gdsn(node)
# "x"

name.gdsn(node, fullname=TRUE)
# "list/x"

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

objdesp.gdsn	<i>Variable description</i>
--------------	-----------------------------

Description

Get the description of a GDS node.

Usage

```
objdesp.gdsn(node)
```

Arguments

node an object of class `gdsn.class`, a GDS node

Value

Returns a list:

name	the variable name of a specified node
fullname	the full name of a specified node
storage	the storage mode in the GDS file
trait	the description of data field, like "Int8"

type	a factor indicating the storage mode in R: Label – a label node, Folder – a directory, VFolder – a virtual folder linking to another GDS file, Raw – raw data (addfile.gdsn), Integer – integers, Factor – factor values, Logical – logical values (FALSE, TRUE and NA), Real – floating numbers, String – characters, Unknown – unknown type
is.array	indicates whether it is array-type
dim	the dimension of data field
encoder	encoder for compressed data, such like "ZIP"
compress	the compression method: "", "ZIP.max", etc
cpratio	data compression ratio, NaN indicates no compression
size	the size of data stored in the GDS file
good	logical, indicates the state of GDS file, e.g., FALSE if the virtual folder fails to link the target GDS file
hidden	logical, TRUE if it is a hidden object
message	if applicable, messages of the GDS node, such like error messages, log information
param	the parameters, used in add.gdsn , like "maxlen", "offset", "scale"

objdesp.gdsn(node3)

# close the GDS file
closefn.gds(f)
```

```
# delete the temporary file
unlink("test.gds", force=TRUE)
```

openfn.gds *Open a GDS file*

Description

Open an existing file of CoreArray Genomic Data Structure (GDS) for reading or writing.

Usage

```
openfn.gds(filename, readonly=TRUE, allow.duplicate=FALSE, allow.fork=FALSE)
```

Arguments

filename	the file name of a GDS file to be opened
readonly	if TRUE, the file is opened read-only; otherwise, it is allowed to write data to the file
allow.duplicate	if TRUE, it is allowed to open a GDS file with read-only mode when it has been opened in the same R session
allow.fork	TRUE for parallel environment using forking, see details

Details

This function opens an existing GDS file for reading (or, if `readonly=FALSE`, for writing). To create a new GDS file, use [createfn.gds](#) instead.

If the file is opened read-only, all data in the file are not allowed to be changed, including hierarchical structure, variable names, data fields, etc.

[mclapply](#) and [mcmapply](#) in the R package `parallel` rely on unix forking. However, the forked child process inherits copies of the parent's set of open file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent. This means that the two descriptors share open file status flags, current file offset, and signal-driven I/O attributes. The sharing of file description can cause a serious problem (wrong reading, even program crashes), when child processes read or write the same GDS file simultaneously. `allow.fork=TRUE` adds additional file operations to avoid any conflict using forking. The current implementation does not support writing in forked processes.

Value

Return an object of class [gds.class](#).

filename	the file name to be created
id	internal file id, an integer
root	an object of class gdsn.class , the root of hierarchical structure
readonly	whether it is read-only or not

Author(s)

Xiuwen Zheng

References<http://github.com/zhengxwen/gdsfmt>**See Also**[createfn.gds](#), [closefn.gds](#)**Examples**

```
# create a GDS file
f <- createfn.gds("test.gds")

# add a list to "test.gds"
node <- add.gdsn(f, name="list", val=list(x=c(1,2), y=c("T","B","C"), z=TRUE))
# close
closefn.gds(f)

# open the same file
f <- openfn.gds("test.gds")

# read
(node <- index.gdsn(f, "list"))
read.gdsn(node)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

`permdim.gdsn`*Array Transposition*

Description

Transpose an array by permuting its dimensions.

Usage`permdim.gdsn(node, dimidx, target=NULL)`**Arguments**

<code>node</code>	an object of class <code>gdsn.class</code> , a GDS node
<code>dimidx</code>	the subscript permutation vector, and it should be a permutation of the integers <code>1:n</code> , where <code>n</code> is the number of dimensions
<code>target</code>	if it is not NULL, the transposed data are saved to target

Value

None.

permdim.gdsn(node, c(3,2,4,1))
stopifnot(identical(aperm(mat, c(3,2,4,1)), read.gdsn(node)))

mat <- read.gdsn(node)
permdim.gdsn(node, c(2,3,1,4))
stopifnot(identical(aperm(mat, c(2,3,1,4)), read.gdsn(node)))

# close the GDS file
closefn.gds(f)

# remove unused space after permuting dimensions
cleanup.gds("test.gds")
```

```
# delete the temporary file
unlink("test.gds", force=TRUE)
```

```
print.gds.class      Show the information of class "gds.class" and "gdsn.class"
```

Description

Displays the contents of "gds.class" (a GDS file) and "gdsn.class" (a GDS node).

Usage

```
## S3 method for class 'gds.class'
print(x, ...)
## S3 method for class 'gdsn.class'
print(x, expand=TRUE, all=FALSE, attribute=FALSE,
      attribute.trim=FALSE, ...)
## S4 method for signature 'gdsn.class'
show(object)
```

Arguments

x	an object of class <code>gds.class</code> , a GDS file; or <code>gdsn.class</code> , a GDS node
object	an object of class <code>gds.class</code> , the number of elements in the preview can be specified via the option <code>getOption("gds.preview.num", 6L)</code> , while 6L is the default value
expand	whether enumerate all of child nodes
all	if FALSE, hide GDS nodes with an attribute "R.invisible"
attribute	if TRUE, show the attribute(s)
attribute.trim	if TRUE, trim the attribute information if it is too long
...	the arguments passed to or from other methods

Value

None.

Author(s)

Xiuwen Zheng

References

<http://github.com/zhengxwen/gdsfmt>

Examples

```
# create a GDS file
f <- createfn.gds("test.gds")

add.gdsn(f, "int", 1:100)
add.gdsn(f, "int.matrix", matrix(1:(50*100), nrow=100, ncol=50))
put.attr.gdsn(index.gdsn(f, "int.matrix"), "int", 1:10)

print(f, all=TRUE)
print(f, all=TRUE, attribute=TRUE)
print(f, all=TRUE, attribute=TRUE, attribute.trim=FALSE)

show(index.gdsn(f, "int"))
show(index.gdsn(f, "int.matrix"))

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

put.attr.gdsn

Add an attribute into a GDS node

Description

Add an attribute to a GDS node.

Usage

```
put.attr.gdsn(node, name, val=NULL)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
name	the name of an attribute
val	the value of an attribute, or a <code>gdsn.class</code> object

Details

Missing values are allowed in a numerical attribute, but not allowed for characters or logical values. Missing characters are converted to "NA", and missing logical values are converted to FALSE.

If val is a `gdsn.class` object, copy all attributes to node.

Value

None.

put.attr.gdsn(node2, val=node)
get.attr.gdsn(node2)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

read.gdsn

Read data field of a GDS node

Description

Get data from a GDS node.

Usage

```
read.gdsn(node, start=NULL, count=NULL,
  simplify=c("auto", "none", "force"), .useraw=FALSE, .value=NULL,
  .substitute=NULL)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
start	a vector of integers, starting from 1 for each dimension component
count	a vector of integers, the length of each dimension. As a special case, the value "-1" indicates that all entries along that dimension should be read, starting from start
simplify	if "auto", the result is collapsed to be a vector if possible; "force", the result is forced to be a vector
.useraw	use R RAW storage mode if integers can be stored in a byte, to reduce memory usage
.value	a vector of values to be replaced in the original data array, or NULL for nothing
.substitute	a vector of values after replacing, or NULL for nothing; <code>length(.substitute)</code> should be one or <code>length(.value)</code> ; if <code>length(.substitute) = length(.value)</code> , it is a mapping from <code>.value</code> to <code>.substitute</code>

Details

start, count: the values in data are taken to be those in the array with the leftmost subscript moving fastest.

Value

Return an array, list, or data.frame.

# create a GDS file
f <- createfn.gds("test.gds")

add.gdsn(f, "vector", 1:128)
add.gdsn(f, "list", list(X=1:10, Y=seq(1, 10, 0.25)))
add.gdsn(f, "data.frame", data.frame(X=1:19, Y=seq(1, 10, 0.5)))
add.gdsn(f, "matrix", matrix(1:12, ncol=4))

f

read.gdsn(index.gdsn(f, "vector"))
read.gdsn(index.gdsn(f, "list"))
read.gdsn(index.gdsn(f, "data.frame"))
```

```

# the effects of 'simplify'
read.gdsn(index.gdsn(f, "matrix"), start=c(2,2), count=c(-1,1))
# [1] 5 6 <- a vector

read.gdsn(index.gdsn(f, "matrix"), start=c(2,2), count=c(-1,1),
          simplify="none")
#      [,1] <- a matrix
# [1,]    5
# [2,]    6

read.gdsn(index.gdsn(f, "matrix"), start=c(2,2), count=c(-1,3))
read.gdsn(index.gdsn(f, "matrix"), start=c(2,2), count=c(-1,3),
          .value=c(12,5), .substitute=NA)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)

```

readex.gdsn

Read data field of a GDS node with a selection

Description

Get data from a GDS node with subset selection.

Usage

```

readex.gdsn(node, sel=NULL, simplify=c("auto", "none", "force"),
            .useraw=FALSE, .value=NULL, .substitute=NULL)

```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
sel	a list of m logical vectors, where m is the number of dimensions of node and each logical vector should have the same size of dimension in node
simplify	if "auto", the result is collapsed to be a vector if possible; "force", the result is forced to be a vector
.useraw	use R RAW storage mode if integers can be stored in a byte, to reduce memory usage
.value	a vector of values to be replaced in the original data array, or NULL for nothing
.substitute	a vector of values after replacing, or NULL for nothing; <code>length(.substitute)</code> should be one or <code>length(.value)</code> ; if <code>length(.substitute) = length(.value)</code> , it is a mapping from <code>.value</code> to <code>.substitute</code>

Details

If `sel` is a list of numeric vectors, the internal method converts the numeric vectors to logical vectors first, extract data with logical vectors, and then call `[]` to reorder or expand data.

Value

Return an array.

closefn.gdsn(f)
```

```
# delete the temporary file
unlink("test.gds", force=TRUE)
```

readmode.gdsn	<i>Switch to read mode in the compression settings</i>
---------------	--

Description

Switch to read mode for a GDS node with respect to its compression settings.

Usage

```
readmode.gdsn(node)
```

Arguments

node an object of class [gdsn.class](#), a GDS node

Details

After the compressed data field is created, it is in writing mode. Users can add new data to the compressed data field, but can not read data from the data field. Users have to call `readmode.gdsn` to finish writing, before reading any data from the compressed data field.

Once switch to the read mode, users can not add more data to the data field. If users would like to append more data or modify the data field, please call `compression.gdsn(node, compress="")` to decompress data first.

Value

Return node.

Author(s)

Xiuwen Zheng

[compression.gdsn](#), [add.gdsn](#)

Examples

```
# create a GDS file
f <- createfn.gdsn("test.gds")

# common types
n <- add.gdsn(f, "int", val=1:100, compress="ZIP")

# you can not read the variable "int" because of writing mode
# read.gdsn(n)

readmode.gdsn(n)

# now you can read "int"
read.gdsn(n)

# close the GDS file
closefn.gdsn(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

rename.gdsn

Rename a GDS node

Description

Rename a GDS node.

Usage

```
rename.gdsn(node, newname)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
newname	the new name of a specified node

Details

CoreArray hierarchical structure does not allow duplicate names in the same folder.

Value

None.

# create a GDS file
f <- createfn.gds("test.gds")
n <- add.gdsn(f, "old.name", val=1:10)
f

rename.gdsn(n, "new.name")
f

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

setdim.gdsn	<i>Set the dimension of data field</i>
-------------	--

Description

Assign new dimensions to the data field of a GDS node.

Usage

```
setdim.gdsn(node, valdim, permute=FALSE)
```

Arguments

node	an object of class gdsn.class , a GDS node
valdim	the new dimension(s) for the array to be created, which is a vector of length one or more giving the maximal indices in each dimension. The values in data are taken to be those in the array with the leftmost subscript moving fastest. The last entry could be ZERO. If the total number of elements is zero, gdsfmt does not allocate storage space. NA is treated as 0.
permute	if TRUE, the elements are rearranged to preserve their relative positions in each dimension of the array

Value

Returns node.

read.gdsn(n)

setdim.gdsn(n, c(6, 4))
read.gdsn(n)

setdim.gdsn(n, c(8, 5), permute=TRUE)
read.gdsn(n)

setdim.gdsn(n, c(3, 4), permute=TRUE)
read.gdsn(n)

n <- add.gdsn(f, "bit3", val=1:24, storage="bit3")
read.gdsn(n)

setdim.gdsn(n, c(6, 4))
read.gdsn(n)

setdim.gdsn(n, c(8, 5), permute=TRUE)
read.gdsn(n)

setdim.gdsn(n, c(3, 4), permute=TRUE)
read.gdsn(n)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

showfile.gds

Enumerate opened GDS files

Description

Enumerate all opened GDS files

Usage

```
showfile.gds(closeall=FALSE, verbose=TRUE)
```

Arguments

closeall	if TRUE, close all GDS files
verbose	if TRUE, show information

Value

A list of `gds.class` objects.

Author(s)

Xiuwen Zheng

References

<http://github.com/zhengxwen/gdsfmt>

Examples

```
# create a GDS file
f <- createfn.gds("test.gds")

add.gdsn(f, "int", val=1:10000)

showfile.gds()

showfile.gds(closeall=TRUE)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

summarize.gdsn

GDS object Summaries

Description

Get the summaries of a GDS node.

Usage

```
summarize.gdsn(node)
```

Arguments

node	an object of class <code>gdsn.class</code> , a GDS node
------	---

Value

A list including

min	the minimum value
max	the maximum value
num_na	the number of invalid numbers or NA
decimal	the count of each decimal (integer, 0.1, 0.01, ..., or other)

Author(s)

Xiuwen Zheng

References<http://github.com/zhengxwen/gdsfmt>**Examples**

```
f <- createfn.gds("test.gds")

n1 <- add.gdsn(f, "x", seq(1, 10, 0.1), storage="float")
n2 <- add.gdsn(f, "y", seq(1, 10, 0.1), storage="double")
n3 <- add.gdsn(f, "int", c(1:100, NA, 112, NA), storage="int")
n4 <- add.gdsn(f, "int8", c(1:100, NA, 112, NA), storage="int8")

summarize.gdsn(n1)
summarize.gdsn(n2)
summarize.gdsn(n3)
summarize.gdsn(n4)

closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

`sync.gds`*Synchronize a GDS file*

Description

Write the data cached in memory to disk.

Usage

```
sync.gds(gdsfile)
```

Arguments

`gdsfile` An object of class `gds.class`, a GDS file

Details

For better performance, Data in a GDS file are usually cached in memory. Keep in mind that the new file may not actually be written to disk, until `closefn.gds` or `sync.gds` is called. Anyway, when R shuts down, all GDS files created or opened would be automatically closed.

Value

None.

Author(s)

Xiuwen Zheng

sync.gds(f)

f
get.attr.gdsn(node)

# close the GDS file
closefn.gds(f)

# delete the temporary file
unlink("test.gds", force=TRUE)
```

system.gds

Get the parameters in the GDS system

Description

Get a list of parameters in the GDS system

Usage

```
system.gds()
```

Value

A list including

```
num.logical.core      the number of logical cores
l1i.cache.size       L1 instruction cache
l1d.cache.size       L1 data cache
l2.cache.size        L2 data cache
l3.cache.size        L3 data cache
l4.cache.size        L4 data cache
compression.encoder  compression/decompression algorithms
```

`compiler.flag` SIMD instructions supported by the compiler
`class.list` class list in the GDS system
`options` list all options associated with GDS format or packages

system.gds()
```

<code>write.gdsn</code>	<i>Write data to a GDS node</i>
-------------------------	---------------------------------

Description

Write data to a GDS node.

Usage

```
write.gdsn(node, val, start=NULL, count=NULL, check=TRUE)
```

Arguments

<code>node</code>	an object of class <code>gdsn.class</code> , a GDS node
<code>val</code>	the data to be written
<code>start</code>	a vector of integers, starting from 1 for each dimension
<code>count</code>	a vector of integers, the length of each dimension
<code>check</code>	if TRUE, a warning will be given when <code>val</code> is character and there are missing values in <code>val</code>

Details

`start`, `count`: The values in data are taken to be those in the array with the leftmost subscript moving fastest.

`start` and `count` should both exist or be missing. If `start` and `count` are both missing, the dimensions and values of `val` will be assigned to the data field.

GDS format does not support missing characters NA, and any NA will be converted to a blank string "".

Value

None.
