Repository Bioconductor 3.18

Date/Publication 2024-01-09

Author Robert Gentleman [aut], Vincent J. Carey [aut], Wolfgang Huber [aut], Florian Hahne [aut], Emmanuel Taiwo [ctb] (howtogenefilter vignette translation from Sweave to RMarkdown / HTML.), Khadijah Amusat [ctb] (Converted genefilter vignette from Sweave to RMarkdown / HTML.), Bioconductor Package Maintainer [cre]
**Description**

Anova returns a function of one argument with bindings for `cov` and `p`. The function, when evaluated, performs an ANOVA using `cov` as the covariate. It returns `TRUE` if the p value for a difference in means is less than `p`.

**Usage**

```r
Anova(cov, p=0.05, na.rm=TRUE)
```
**Arguments**

- **cov**: The covariate. It must have length equal to the number of columns of the array that `Anova` will be applied to.
- **p**: The p-value for the test.
- **na.rm**: If set to `TRUE` any `NA`'s will be removed.

**Details**

The function returned by `Anova` uses `lm` to fit a linear model of the form `lm(x ~ cov)`, where `x` is the set of gene expressions. The F statistic for an overall effect is computed and if it has a `p`-value less than `p` the function returns `TRUE`, otherwise it returns `FALSE` for that gene.

**Value**

`Anova` returns a function with bindings for `cov` and `p` that will perform a one-way ANOVA.

The covariate can be continuous, in which case the test is for a linear effect for the covariate.

**Author(s)**

R. Gentleman

**See Also**

`kOverA`, `lm`

**Examples**

```r
set.seed(123)
af <- Anova(c(rep(1,5),rep(2,5)), .01)
af(rnorm(10))
```

---

**coxfilter**

*A filter function for univariate Cox regression.*

**Description**

A function that performs Cox regression with bindings for `surt`, `cens`, and `p` is returned. This function filters genes according to the attained p-value from a Cox regression using `surt` as the survival times, and `cens` as the censoring indicator. It requires `survival`.

**Usage**

```r
coxfilter(surt, cens, p)
```
Arguments

surt  Survival times.
cens  Censoring indicator.
p     The p-value to use in filtering.

Value

Calls to the `coxph` function in the `survival` library are used to fit a Cox model. The filter function returns `TRUE` if the p-value in the fit is less than `p`.

Author(s)

R. Gentleman

See Also

`Anova`

Examples

```r
set.seed(-5)
sfun <- coxfilter(rexp(10), ifelse(runif(10) < .7, 1, 0), .05)
ffun <- filterfun(sfun)
dat <- matrix(rnorm(1000), ncol=10)
out <- genefilter(dat, ffun)
```

---

`cv`  
*Arguments*

A filter function for the coefficient of variation.

**Description**

`cv` returns a function with values for `a` and `b` bound. This function takes a single argument. It computes the coefficient of variation for the input vector and returns `TRUE` if the coefficient of variation is between `a` and `b`. Otherwise it returns `FALSE`.

**Usage**

`cv(a=1, b=Inf, na.rm=TRUE)`

**Arguments**

- `a`  The lower bound for the cv.
- `b`  The upper bound for the cv.
- `na.rm`  If set to `TRUE` any NA’s will be removed.

**Details**

The coefficient of variation is the standard deviation divided by the absolute value of the mean.
Value

It returns a function of one argument. The function has an environment with bindings for \( a \) and \( b \).

Author(s)

R. Gentleman

pOverA, kOverA

Examples

```r
set.seed(-3)
cvfun <- cv(1, 10)
cvfun(rnorm(10, 10))
cvfun(rnorm(10))
```

dist2

Calculate an \( n \)-by-\( n \) matrix by applying a function to all pairs of columns of an \( m \)-by-\( n \) matrix.

Description

Calculate an \( n \)-by-\( n \) matrix by applying a function to all pairs of columns of an \( m \)-by-\( n \) matrix.

Usage

```r
dist2(x, fun, diagonal=0)
```

Arguments

- \( x \): A matrix.
- \( \text{fun} \): A symmetric function of two arguments that may be columns of \( x \).
- \( \text{diagonal} \): The value to be used for the diagonal elements of the resulting matrix.

Details

With the default value of \( \text{fun} \), this function calculates for each pair of columns of \( x \) the mean of the absolute values of their differences (which is proportional to the L1-norm of their difference). This is a distance metric.

The implementation assumes that \( \text{fun}(x[,i], x[,j]) \) can be evaluated for all pairs of \( i \) and \( j \) (see examples), and that \( \text{fun} \) is symmetric, i.e. \( \text{fun}(a, b) = \text{fun}(b, a) \). \( \text{fun}(a, a) \) is not actually evaluated, instead the value of \( \text{diagonal} \) is used to fill the diagonal elements of the returned matrix.

Note that \textit{dist} computes distances between rows of \( x \), while this function computes relations between columns of \( x \) (see examples).
Value

A symmetric matrix of size $n \times n$.

Author(s)

Wolfgang Huber, James Reid

Examples

```r
# example matrix
z = matrix(1:15693, ncol=3)
matL1 = dist2(z)
matL2 = dist2(z, fun=function(a,b) sqrt(sum((a-b)^2, na.rm=TRUE)))
euc = as.matrix(dist(t(z)));
stopifnot(identical(dim(matL2), dim(euc)),
all(euc==matL2))
```

---

**eSetFilter**

* A function to filter an *eSet* object

**Description**

Given a Bioconductor’s ExpressionSet object, this function filters genes using a set of selected filters.

**Usage**

```r
eSetFilter(eSet)
getFilterNames()
getFuncDesc(lib = "genefilter", funcs = getFilterNames())
getRdAsText(lib)
parseDesc(text)
parseArgs(text)
showESet(eSet)
setESetArgs(filter)
isESet(eSet)
```

**Arguments**

- **eSet**: an ExpressionSet object
- **lib**: a character string for the name of an R library where functions of interests reside
- **funcs**: a vector of character strings for names of functions of interest
- **text**: a character of string from a file (e. g. description, argument, ..) filed of an Rd file for a function
- **filter**: a character string for the name of a filter function
filtered_p

Details

These functions are deprecated. Please use the 'iSee' package instead.

A set of filters may be selected to filter genes in through each of the filters in the order the filters have been selected

Value

A logical vector of length equal to the number of rows of 'expr'. The values in that vector indicate whether the corresponding row of 'expr' passed the set of filter functions.

genefilter

Examples

if( interactive() ) {
  data(sample.ExpressionSet)
  res <- eSetFilter(sample.ExpressionSet)
}

filtered_p

Compute and adjust p-values, with filtering

Description

Given filter and test statistics in the form of unadjusted p-values, or functions able to compute these statistics from the data, filter and then correct the p-values across a range of filtering stringencies.

Usage

filtered_p(filter, test, theta, data, method = "none")
filtered_R(alpha, filter, test, theta, data, method = "none")

Arguments

alpha        A cutoff to which p-values, possibly adjusted for multiple testing, will be compared.
filter       A vector of stage-one filter statistics, or a function which is able to compute this vector from data, if data is supplied.
test         A vector of unadjusted p-values, or a function which is able to compute this vector from the filtered portion of data, if data is supplied. The option to supply a function is useful when the value of the test statistic depends on which hypotheses are filtered out at stage one. (The limma t-statistic is an example.)
theta A vector with one or more filtering fractions to consider. Actual cutoffs are then computed internally by applying \texttt{quantile} to the filter statistics contained in (or produced by) the filter argument.

data If filter and/or test are functions rather than vectors of statistics, they will be applied to data. The functions will be passed the whole data object, and must work over rows, etc. themselves as appropriate.

method The unadjusted p-values contained in (or produced by) test will be adjusted for multiple testing after filtering, using the \texttt{p.adjust} function in the \texttt{stats} package. See the method argument there for options.

\texttt{p}

Value

For \texttt{filtered\_p}, a matrix of p-values, possible adjusted for multiple testing, with one row per null hypothesis and one column per filtering fraction given in theta. For a given column, entries which have been filtered out are \texttt{NA}.

For \texttt{filtered\_R}, a count of the entries in the \texttt{filtered\_p} result which are less than \texttt{alpha}.

\begin{verbatim}
fILTERFUN

arg_def filterfun

\begin{verbatim}
 filterfun(...)  Creates a first FALSE exiting function from the list of filter functions it is given.
\end{verbatim}

Description

This function creates a function that takes a single argument. The filtering functions are bound in the environment of the returned function and are applied sequentially to the argument of the returned function. When the first filter function evaluates to FALSE the function returns FALSE otherwise it returns TRUE.

Usage

\texttt{filterfun(...)}

Arguments

\begin{verbatim}
  ... Filtering functions.
\end{verbatim}
Value

filterfun returns a function that takes a single argument. It binds the filter functions given to it in the environment of the returned function. These functions are applied sequentially (in the order they were given to filterfun). The function returns FALSE (and exits) when the first filter function returns FALSE otherwise it returns TRUE.

cvfun <- cv(.5,2.5)
ffun <- filterfun(cvfun)
which <- genefilter(x, ffun)

---

filter_volcano

Volcano plot for overall variance filtering

Description

Generate a volcano plot contrasting p-value with fold change (on the log scale), in order to visualize the effect of filtering on overall variance and also assign significance via p-value.

Usage

filter_volcano(
d, p, S,
n1, n2,
alpha, S_cutoff,
cex = 0.5, pch = 19,
xlab = expression(paste(log[2], " fold change")),
ylab = expression(paste("-", log[10], " p")),
cols = c("grey80", "grey50", "black"),
ltys = c(1, 3),
use_legend = TRUE,
... )
findLargest

Arguments

d  Fold changes, typically on the log scale, base 2.
p  The p-values
S  The overall standard deviation filter statistics, i.e., the square roots of the overall variance filter statistics.
n1  Sample size for group 1.
n2  Sample size for group 2.
alpha  Significance cutoff used for p-values.
S_cutoff  Filter cutoff used for the overall standard deviation in S.
cex  Point size for plotting.
pch  Point character for plotting.
xlab  Label for x-axis.
ylab  Label for y-axis.
cols  A vector of three colors used for plotting. These correspond to filtered data, data which pass the filter but are insignificant, and data pass the filter and are also statistically significant.
lty  The induced bound on log-scale fold change is plotted, as is the significance cutoff for data passing the filter. The lty argument gives line styles for these drawing these two thresholds on the plot.
use_legend  Should a legend for point color be produced?
...  Other arguments for plot.

Examples

# See the vignette: Diagnostic plots for independent filtering

findLargest(gN, testStat, data = "hgu133plus2")

Description

Most microarrays have multiple probes per gene (Entrez). This function finds all replicates, and then selects the one with the largest value of the test statistic.

Usage

findLargest(gN, testStat, data = "hgu133plus2")
**Arguments**

- **gN**: A vector of probe identifiers for the chip.
- **testStat**: A vector of test statistics, of the same length as gN with the per probe test statistics.
- **data**: The character string identifying the chip.

**Details**

All the probe identifiers, gN, are mapped to Entrez Gene IDs and the duplicates determined. For any set of probes that map to the same Gene ID, the one with the largest test statistic is found. The return vector is the named vector of selected probe identifiers. The names are the Entrez Gene IDs. This could be extended in different ways, such as allowing the user to use a different selection criterion. Also, matching on different identifiers seems like another alternative.

**Value**

A named vector of probe IDs. The names are Entrez Gene IDs.

**Author(s)**

R. Gentleman

**See Also**

- sapply

**Examples**

```r
library("hgu95av2.db")
set.seed(124)
gN <- sample(ls(hgu95av2ENTREZID), 200)
stats <- rnorm(200)
findLargest(gN, stats, "hgu95av2")
```

---

**Description**

The `gapFilter` looks for genes that might usefully discriminate between two groups (possibly unknown at the time of filtering). To do this we look for a gap in the ordered expression values. The gap must come in the central portion (we exclude jumps in the initial Prop values or the final Prop values). Alternatively, if the IQR for the gene is large that will also pass our test and the gene will be selected.
Usage

gapFilter(Gap, IQR, Prop, na.rm=TRUE, neg.rm=TRUE)

Arguments

- **Gap**: The size of the gap required to pass the test.
- **IQR**: The size of the IQR required to pass the test.
- **Prop**: The proportion (or number) of samples to exclude at either end.
- **na.rm**: If TRUE then NA’s will be removed before processing.
- **neg.rm**: If TRUE then negative values in x will be removed before processing.

Details

As stated above we are interested in

Value

A function that returns either TRUE or FALSE depending on whether the vector supplied has a gap larger than Gap or an IQR (inter quartile range) larger than IQR. For computing the gap we want to exclude a proportion, Prop from either end of the sorted values. The reason for this requirement is that genes which differ in expression levels only for a few samples are not likely to be interesting.

ttest, genefilter

Examples

```r
set.seed(256)
x <- c(rnorm(10, 100, 3), rnorm(10, 100, 10))
y <- x + c(rep(0, 10), rep(100, 10))
tmp <- rbind(x, y)
Gfilter <- gapFilter(200, 100, 5)
ffun <- filterfun(Gfilter)
genefilter(tmp, ffun)
```
Description

genefilter filters genes in the array expr using the filter functions in flist. It returns an array of logical values (suitable for subscripting) of the same length as there are rows in expr. For each row of expr the returned value is TRUE if the row passed all the filter functions. Otherwise it is set to FALSE.

Usage

genefilter(expr, flist)

Arguments

eexpr A matrix or ExpressionSet that the filter functions will be applied to.
flist A list of filter functions to apply to the array.

Details

This package uses a very simple but powerful protocol for filtering genes. The user simply constructs any number of tests that they want to apply. A test is simply a function (as constructed using one of the many helper functions in this package) that returns TRUE if the gene of interest passes the test (or filter) and FALSE if the gene of interest fails.

The benefit of this approach is that each test is constructed individually (and can be tested individually). The tests are then applied sequentially to each gene. The function returns a logical vector indicating whether the gene passed all tests functions or failed at least one of them.

Users can construct their own filters. These filters should accept a vector of values, corresponding to a row of the expr object. The user defined function should return a length 1 logical vector, with value TRUE or FALSE. User-defined functions can be combined with filterfun, just as built-in filters.

Value

A logical vector of length equal to the number of rows of expr. The values in that vector indicate whether the corresponding row of expr passed the set of filter functions.

Author(s)

R. Gentleman

See Also

genefilter, kOverA
Examples

```r
set.seed(-1)
f1 <- kOverA(5, 10)
flist <- filterfun(f1)
exprA <- matrix(rnorm(1000, 10), ncol = 10)
ans <- genefilter(exprA, flist)
```

Description  
These functions are provided for compatibility with older versions of ‘genefilter’ only, and will be defunct at the next release.

Details  
The following functions are deprecated and will be made defunct; use the replacement indicated below:

- eSetFilter
- getFilterNames
- getFuncDesc
- getRdAsText
- parseDesc
- parseArgs
- showESet
- setESetArgs
- isESet

Description  
Finds genes that have similar patterns of expression.

Usage  
```r
genefinder(X, ilist, numResults=25, scale="none", weights, method="euclidean")
```
Arguments

- **X**: A numeric matrix where columns represent patients and rows represent genes.
- **ilist**: A vector of genes of interest. Contains indices of genes in matrix X.
- **numResults**: Number of results to display, starting from the least distance to the greatest.
- **scale**: One of "none", "range", or "zscore". Scaling is carried out separately on each row.
- **weights**: A vector of weights applied across the columns of X. If no weights are supplied, no weights are applied.
- **method**: One of "euclidean", "maximum", "manhattan", "canberra", "correlation", "binary".

Details

If the scale option is "range", then the input matrix is scaled using genescale(). If it is "zscore", then the input matrix is scaled using the scale builtin with no arguments.

The method option specifies the metric used for gene comparisons. The metric is applied, row by row, for each gene specified in ilist.

The "correlation" option for the distance method will return a value equal to 1-correlation(x).

See **dist** for a more detailed description of the distances.

Value

The returned value is a list containing an entry for each gene specified in ilist. Each list entry contains an array of distances for that gene of interest.

J. Gentry and M. Kajen

See Also

- **genescale**

Examples

```
set.seed(12345)

# create some fake expression profiles
m1 <- matrix(1:12, 4, 3)
v1 <- 1
nr <- 2

# find the 2 rows of m1 that are closest to row 1
gefinder(m1, v1, nr, method="euc")

v2 <- c(1,3)
gefinder(m1, v2, nr)
```
genescale (m1, v2, nr, scale="range")

genescale (m1, v2, nr, method="manhattan")

m2 <- matrix (rnorm(100), 10, 10)
v3 <- c(2, 5, 6, 8)
nr2 <- 6
genescale (m2, v3, nr2, scale="zscore")

genescale Scales a matrix or vector.

Description

genescale returns a scaled version of the input matrix m by applying the following formula to each column of the matrix:

\[ y[i] = (x[i] - \min(x))/(\max(x) - \min(x)) \]

Usage

genescale(m, axis=2, method=c("Z", "R"), na.rm=TRUE)

Arguments

- **m**: Input a matrix or a vector with numeric elements.
- **axis**: An integer indicating which axis of m to scale.
- **method**: Either "Z" or "R", indicating whether a Z scaling or a range scaling should be performed.
- **na.rm**: A boolean indicating whether NA's should be removed.

Details

Either the rows or columns of m are scaled. This is done either by subtracting the mean and dividing by the standard deviation ("Z") or by subtracting the minimum and dividing by the range.

Value

A scaled version of the input. If m is a matrix or a dataframe then the dimensions of the returned value agree with that of m, in both cases the returned value is a matrix.

Author(s)

R. Gentleman
half.range.mode

See Also
genefinder, scale

Examples

m <- matrix(1:12, 4, 3)
genescale(m)

Description

For data assumed to be drawn from a unimodal, continuous distribution, the mode is estimated by the “half-range” method. Bootstrap resampling for variance reduction may optionally be used.

Usage

half.range.mode(data, B, B.sample, beta = 0.5, diag = FALSE)

Arguments

data A numeric vector of data from which to estimate the mode.
B Optionally, the number of bootstrap resampling rounds to use. Note that B = 1 resamples 1 time, whereas omitting B uses data as is, without resampling.
B.sample If bootstrap resampling is requested, the size of the bootstrap samples drawn from data. Default is to use a sample which is the same size as data. For large data sets, this may be slow and unnecessary.
beta The fraction of the remaining range to use at each iteration.
diag Print extensive diagnostics. For internal testing only... best left FALSE.

Details

Briefly, the mode estimator is computed by iteratively identifying densest half ranges. (Other fractions of the current range can be requested by setting beta to something other than 0.5.) A densest half range is an interval whose width equals half the current range, and which contains the maximal number of observations. The subset of observations falling in the selected densest half range is then used to compute a new range, and the procedure is iterated. See the references for details.

If bootstrapping is requested, B half-range mode estimates are computed for B bootstrap samples, and their average is returned as the final estimate.

Value

The mode estimate.

)
M.list <- list(
  Simple = apply( X, 2, half.range.mode ),
  BS = apply( X, 2, half.range.mode, B = 100 )
)

if(interactive()){
  boxplot( M.list, main = "Effect of bootstrapping" )
  abline( h = 0, col = "red" )
}
```
kappa_p

Compute proportionality constant for fold change bound.

Description
Filtering on overall variance induces a lower bound on fold change. This bound depends on the significance of the evidence against the null hypothesis, an is a multiple of the cutoff used for an overall variance filter. It also depends on sample size in both of the groups being compared. These functions compute the multiplier for the supplied p-values or t-statistics.

Usage
kappa_p(p, n1, n2 = n1)
kappa_t(t, n1, n2 = n1)

Arguments
- **p**: The p-values at which to compute the multiplier.
- **t**: The t-statistics at which to compute the multiplier.
- **n1**: Sample size for class 1.
- **n2**: Sample size for class 2.

Value
A vector of multipliers: one per p-value or t-static in p or t.

Examples
# See the vignette: Diagnostic plots for independent filtering

k0verA

A filter function for k elements larger than A.

Description
k0verA returns a filter function with bindings for k and A. This function evaluates to TRUE if at least k of the arguments elements are larger than A.

Usage
k0verA(k, A=100, na.rm=TRUE)
Arguments

A  The value you want to exceed.
k  The number of elements that have to exceed A.
na.rm  If set to TRUE any NA’s will be removed.

Value

A function with bindings for A and k.

Author(s)

R. Gentleman

---

Filtering of Features in an ExpressionSet

Description

The function `nsFilter` tries to provide a one-stop shop for different options of filtering (removing) features from an ExpressionSet. Filtering features exhibiting little variation, or a consistently low signal, across samples can be advantageous for the subsequent data analysis (Bourgon et al.). Furthermore, one may decide that there is little value in considering features with insufficient annotation.

Usage

```r
nsFilter(eset, require.entrez=TRUE,
require.GOBP=FALSE, require.GOCC=FALSE,
require.GOMF=FALSE, require.CytoBand=FALSE,
remove.dupEntrez=TRUE, var.func=IQR,
var.cutoff=0.5, var.filter=TRUE,
filterByQuantile=TRUE, feature.exclude="^AFFX", ...)
```

```r
varFilter(eset, var.func=IQR, var.cutoff=0.5, filterByQuantile=TRUE)
```

```r
featureFilter(eset, require.entrez=TRUE,
require.GOBP=FALSE, require.GOCC=FALSE,
require.GOMF=FALSE, require.CytoBand=FALSE,
remove.dupEntrez=TRUE, feature.exclude="^AFFX")
```

Arguments

- `eset` : an ExpressionSet object
- `var.func` : The function used as the per-feature filtering statistic. This function should return a numeric vector of length one when given a numeric vector as input.
- `var.filter` : A logical indicating whether to perform filtering based on `var.func`.
- `filterByQuantile` : A logical indicating whether `var.cutoff` is to be interpreted as a quantile of all `var.func` values (the default), or as an absolute value.
var.cutoff  A numeric value. If var.filter is TRUE, features whose value of var.func is
less than either: the var.cutoff-quantile of all var.func values (if filterByQuantile
is TRUE), or var.cutoff (if filterByQuantile is FALSE) will be removed.

require.entrez  If TRUE, filter out features without an Entrez Gene ID annotation. If using an
annotation package where an identifier system other than Entrez Gene IDs is
used as the central ID, then that ID will be required instead.

require.GOBO, require.GOC, require.GOMF
  If TRUE, filter out features whose target genes are not annotated to at least one
GO term in the BP, CC or MF ontology, respectively.

require.CytoBand
  If TRUE, filter out features whose target genes have no mapping to cytoband
locations.

remove.dupEntrez
  If TRUE and there are features mapping to the same Entrez Gene ID (or equiva-
 lent), then the feature with the largest value of var.func will be retained and
the other(s) removed.

feature.exclude
  A character vector of regular expressions. Feature identifiers (i.e. value of
featureNames(eset)) that match one of the specified patterns will be filtered
out. The default value is intended to filter out Affymetrix quality control probe
sets.

...  Unused, but available for specializing methods.

Details

In this Section, the effect of filtering on the type I error rate estimation / control of subsequent
hypothesis testing is explained. See also the paper by Bourgon et al.

Marginal type I errors: Filtering on the basis of a statistic which is independent of the test statistic
used for detecting differential gene expression can increase the detection rate at the same marginal
type I error. This is clearly the case for filter criteria that do not depend on the data, such as
the annotation based criteria provided by the nsFilter and featureFilter functions. However,
marginal type I error can also be controlled for certain types of data-dependent criteria. Call \( U_I \)
the stage 1 filter statistic, which is a function that is applied feature by feature, based on whose value
the feature is or is not accepted to pass to stage 2, and which depends only on the data for that
feature and not any other feature, and call \( U_{II} \) the stage 2 test statistic for differential expression.

Sufficient conditions for marginal type-I error control are:

- \( U_I \) the overall (across all samples) variance or mean, \( U_{II} \) the t-statistic (or any other scale
  and location invariant statistic), data normal distributed and exchangeable across samples.
- \( U_I \) the overall mean, \( U_{II} \) the moderated t-statistic (as in limma’s eBayes function), data
  normal distributed and exchangeable.
- \( U_I \) a sample-class label independent function (e.g. overall mean, median, variance, IQR), \( U_{II} \)
  the Wilcoxon rank sum statistic, data exchangeable.

Experiment-wide type I error: Marginal type-I error control provided by the conditions above is
sufficient for control of the family wise error rate (FWER). Note, however, that common false dis-
ccovery rate (FDR) methods depend not only on the marginal behaviour of the test statistics under the
null hypothesis, but also on their joint distribution. The joint distribution can be affected by filtering, even when this filtering leaves the marginal distributions of true-null test statistics unchanged. Filtering might, for example, change correlation structure. The effect of this is negligible in many cases in practice, but this depends on the dataset and the filter used, and the assessment is in the responsibility of the data analyst.

Annotation Based Filtering Arguments require.entrez, require.GOBP, require.GOCC, require.GOMF and require.CytoBand filter based on available annotation data. The annotation package is determined by calling annotation(eset).

Variance Based Filtering The var.filter, var.func, var.cutoff and varByQuantile arguments control numerical cutoff-based filtering. Probes for which var.func returns NA are removed. The default var.func is IQR, which we here define as rowQ(eset, ceiling(0.75 * ncol(eset))) - rowQ(eset, floor(0.25 * ncol(eset))); this choice is motivated by the observation that unexpressed genes are detected most reliably through low variability of their features across samples. Additionally, IQR is robust to outliers (see note below). The default var.cutoff is 0.5 and is motivated by a rule of thumb that in many tissues only 40% of genes are expressed. Please adapt this value to your data and question.

By default the numerical-filter cutoff is interpreted as a quantile, so with the default settings, 50% of the genes are filtered.

Variance filtering is performed last, so that (if varByQuantile=TRUE and remove.dupEntrez=TRUE) the final number of genes does indeed exclude precisely the var.cutoff fraction of unique genes remaining after all other filters were passed.

The stand-alone function varFilter does only var.func-based filtering (and no annotation based filtering). featureFilter does only annotation based filtering and duplicate removal; it always performs duplicate removal to retain the highest-IQR probe for each gene.

Value

For nsFilter a list consisting of:

- eset the filtered ExpressionSet
- filter.log a list giving details of how many probe sets were removed for each filtering step performed.

For both varFilter and featureFilter the filtered ExpressionSet.

Note

IQR is a reasonable variance-filter choice when the dataset is split into two roughly equal and relatively homogeneous phenotype groups. If your dataset has important groups smaller than 25% of the overall sample size, or if you are interested in unusual individual-level patterns, then IQR may not be sensitive enough for your needs. In such cases, you should consider using less robust and more sensitive measures of variance (the simplest of which would be sd).

cv

Examples

```r
ff <- pOverA(p = .1, 10)
ff(1:20)
ff(1:5)
```

---

**rejection_plot**

Plot rejections vs. p-value cutoff

**Description**

Plot the number, or fraction, of null hypotheses rejected as a function of the p-value cutoff. Multiple sets of p-values are accepted, in a list or in the columns of a matrix, in order to permit comparisons.

**Usage**

```r
rejection_plot(p,
col, lty = 1, lwd = 1,
xlab = "p cutoff", ylab = "number of rejections",
xlim = c(0, 1), ylim,
legend = names(p),
at = c("all", "sample"),
n_at = 100,
probability = FALSE,
...)
```

**Arguments**

- **p**
  - The p-values to be used for plotting. These may be in the columns of a matrix, or in the elements of a list. One curve will be generated for each column/element, and all NA entries will be dropped. If column or element names are supplied, they are used by default for a plot legend.

- **col**
  - Colors to be used for each curve plotted. Recycled if necessary. If `col` is omitted, `rainbow` is used to generate a set of colors.

- **lty**
  - Line styles to be used for each curve plotted. Recycled if necessary.

- **lwd**
  - Line widths to be used for each curve plotted. Recycled if necessary.

- **xlab**
  - X-axis text label.

- **ylab**
  - Y-axis text label.

- **xlim**
  - X-axis limits.

- **ylim**
  - Y-axis limits.
legend

Text for legend. Matrix column names or list element names (see p above) are used by default. If NULL, no legend is plotted.

at

Should step functions be plotted with a step at every value in p, or should linear interpolation be used at a sample of points spanning xlim? The latter looks when there are many p-values.

n_at

When at = "sample" is given, how many sample points should be used for interpolation and plotting?

probability

Should the fraction of null hypotheses rejected be reported instead of the count? See the probability argument to hist.

...

Other arguments to pass to the plot call which sets up the axes. Note that the ... argument will not be passed to the lines calls which actually generate the curves.

Value

A list of the step functions used for plotting is returned invisibly.

Author(s)

Richard Bourgon <bourgon@ebi.ac.uk>

Examples

# See the vignette: Diagnostic plots for independent filtering

rowFtests t-tests and F-tests for rows or columns of a matrix

Description

t-tests and F-tests for rows or columns of a matrix, intended to be speed efficient.

Usage

rowttests(x, fac, tstatOnly = FALSE, na.rm = FALSE)
colttests(x, fac, tstatOnly = FALSE, na.rm = FALSE)
fastT(x, ig1, ig2, var.equal = TRUE)
rowFtests(x, fac, var.equal = TRUE)
colFtests(x, fac, var.equal = TRUE)
Arguments

x Numeric matrix. The matrix must not contain NA values. For rowttests and colttests, x can also be an ExpressionSet.

fac Factor which codes the grouping to be tested. There must be 1 or 2 groups for the t-tests (corresponding to one- and two-sample t-test), and 2 or more for the F-tests. If fac is missing, this is taken as a one-group test (i.e. is only allowed for the t-tests). The length of the factor needs to correspond to the sample size: for the row* functions, the length of the factor must be the same as the number of columns of x, for the col* functions, it must be the same as the number of rows of x.

If x is an ExpressionSet, then fac may also be a character vector of length 1 with the name of a covariate in x.

tstatOnly A logical variable indicating whether to calculate p-values from the t-distribution with appropriate degrees of freedom. If TRUE, just the t-statistics are returned. This can be considerably faster.

na.rm A logical variable indicating whether to remove NA values prior to calculation test statistics.

ig1 The indices of the columns of x that correspond to group 1.

ig2 The indices of the columns of x that correspond to group 2.

var.equal A logical variable indicating whether to treat the variances in the samples as equal. If 'TRUE', a simple F test for the equality of means in a one-way analysis of variance is performed. If 'FALSE', an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Details

If fac is specified, rowttests performs for each row of x a two-sided, two-class t-test with equal variances. fac must be a factor of length ncol(x) with two levels, corresponding to the two groups. The sign of the resulting t-statistic corresponds to "group 1 minus group 2". If fac is missing, rowttests performs for each row of x a two-sided one-class t-test against the null hypothesis 'mean=0'.

rowttests and colttests are implemented in C and should be reasonably fast and memory-efficient. fastT is an alternative implementation, in Fortran, possibly useful for certain legacy code. rowFtests and colFtests are currently implemented using matrix algebra in R. Compared to the rowttests and colttests functions, they are slower and use more memory.

Value

A data.frame with columns statistic, p.value (optional in the case of the t-test functions) and dm, the difference of the group means (only in the case of the t-test functions). The row.names of the data.frame are taken from the corresponding dimension names of x.

The degrees of freedom are provided in the attribute df. For the F-tests, if var.equal is 'FALSE', nrow(x)+1 degree of freedoms are given, the first one is the first degree of freedom (it is the same for each row) and the other ones are the second degree of freedom (one for each row).

```
## rowpAUCs

### Methods

Rowwise ROC and pAUC computation

#### Description

Methods for fast rowwise computation of ROC curves and (partial) area under the curve (pAUC) using the simple classification rule \( x > \theta \), where \( \theta \) is a value in the range of \( x \).

#### Usage

\[
\text{rowpAUCs}(x, \text{fac}, p=0.1, \text{flip}=\text{TRUE}, \text{caseNames}=c("1", "2"))
\]

#### Arguments

- \( x \): ExpressionSet or numeric matrix. The matrix must not contain NA values.
Rowwise calculation of Receiver Operating Characteristic (ROC) curves and the corresponding partial area under the curve (pAUC) for a given data matrix or ExpressionSet. The function is implemented in C and thus reasonably fast and memory efficient. Cutpoints (theta) are calculated before the first, in between and after the last data value. By default, both classification rules \( x > \theta \) and \( x < \theta \) are tested and the (partial) area under the curve of the better one of the two is returned. This is only valid for symmetric cases, where the classification is independent of the magnitude of \( x \) (e.g., both over- and under-expression of different genes in the same class). For unsymmetric cases in which you expect \( x \) to be consistently higher/lower in of the two classes (e.g. presence or absence of a single biomarker) set flip=FALSE or use the functionality provided in the \textit{ROC} package. For better control over the classification (i.e., the choice of "Disease" and "Control" class in the sense of the Pepe et al paper), argument fac can be an integer in \([0,1]\) where 1 indicates "Disease" and 0 indicates "Control".

**Value**

An object of class \textit{rowROC} with the calculated specificities and sensitivities for each row and the corresponding pAUCs and AUCs values. See \textit{rowROC} for details.

**Methods**

Methods exist for \textit{rowPAUCs}:

- \texttt{signature(x="matrix", fac="factor")}
- \texttt{rowPAUCs} signature(x="matrix", fac="numeric")
- \texttt{rowPAUCs} signature(x="ExpressionSet")
- \texttt{rowPAUCs} signature(x="ExpressionSet", fac="character")

  plot(r4, area(r2), xlab="function pAUC", ylab="function rowpAUCs",
       main="pAUCs")

  plot(r4, area(rowpAUCs(sample.ExpressionSet[1:nGenes, ],
                  "sex", p=1, flip=FALSE)), xlab="function pAUC", ylab="function rowpAUCs",
       main="pAUCs")

  r4[r4<0.5] <- 1-r4[r4<0.5]
  plot(r4, area(r2), xlab="function pAUC", ylab="function rowpAUCs",
       main="pAUCs")
}
```
Description

A class to model ROC curves and corresponding area under the curve as produced by rowpAUCs.

Objects from the Class

Objects can be created by calls of the form new("rowROC", ...).

Slots

data: Object of class "matrix" The input data.
ranks: Object of class "matrix" The ranked input data.
sens: Object of class "matrix" Matrix of sensitivity values for each gene at each cutpoint.
spec: Object of class "matrix" Matrix of specificity values for each gene at each cutpoint.
pAUC: Object of class "numeric" The partial area under the curve (integrated from 0 to p).
AUC: Object of class "numeric" The total area under the curve.
factor: Object of class "factor" The factor used for classification.
cutpoints: Object of class "matrix" The values of the cutpoints at which specificity and sensitivity was calculated. (Note: the data is ranked prior to computation of ROC curves, the cutpoints map to the ranked data.
caseNames: Object of class "character" The names of the two classification cases.
p: Object of class "numeric" The limit to which pAUC is integrated.

Methods

show signature(object="rowROC") Print nice info about the object.
[ signature(x="rowROC", j="missing") Subset the object according to rows/genes.
plot signature(x="rowROC", y="missing") Plot the ROC curve of the first row of the object along with the pAUC. To plot the curve for a specific row/gene subsetting should be done first (i.e. plot(rowROC[1])).
pAUC signature(object="rowROC", p="numeric", flip="logical") Integrate area under the curve from 0 to p. This method returns a new rowROC object.
AUC signature(object="rowROC") Integrate total area under the curve. This method returns a new rowROC object.
sens signature(object="rowROC") Accessor method for sensitivity slot.
spec signature(object="rowROC") Accessor method for specificity slot.
area signature(object="rowROC", total="logical") Accessor method for pAUC slot.
**rowSds**

Row variance and standard deviation of a numeric array

---

### Description

Row variance and standard deviation of a numeric array

### Usage

```r
rowVars(x, ...)  
rowSds(x, ...)
```

### Arguments

- **x**
  - An array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame.
- **...**
  - Further arguments that get passed on to `rowMeans` and `rowSums`.

---

**Author(s)**

Florian Hahne <fhahne@fhcrc.org>

**References**

**See Also**

`rowpAUCs`

**Examples**

```r
library("Biobase")
data("sample.ExpressionSet")
roc <- rowpAUCs(sample.ExpressionSet, "sex", p=0.5)
roc
area(roc[1:3])

if(interactive()) {
  par(ask=TRUE)
  plot(roc)
  plot(1-spec(roc[1]), sens(roc[2]))
  par(ask=FALSE)
}

pAUC(roc, 0.1)
roc
```
Details

These are very simple convenience functions, the main work is done in rowMeans and rowSums. See the function definition of rowVars, it is very simple.

Value

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. The ‘dimnames’ (or ‘names’ for a vector result) are taken from the original array.

a = matrix(rnorm(1e4), nrow=10)
rowSds(a)
```

shorth

A location estimator based on the shorth

Description

A location estimator based on the shorth

Usage

shorth(x, na.rm=FALSE, tie.action="mean", tie.limit=0.05)

Arguments

x Numeric

na.rm Logical. If TRUE, then non-finite (according to is.finite) values in x are ignored. Otherwise, presence of non-finite or NA values will lead to an error message.

tie.action Character scalar. See details.

tie.limit Numeric scalar. See details.
Details

The shorth is the shortest interval that covers half of the values in x. This function calculates the mean of the x values that lie in the shorth. This was proposed by Andrews (1972) as a robust estimator of location.

Ties: if there are multiple shortest intervals, the action specified in ties.action is applied. Allowed values are mean (the default), max and min. For mean, the average value is considered; however, an error is generated if the start indices of the different shortest intervals differ by more than the fraction tie.limit of length(x). For min and max, the left-most or right-most, respectively, of the multiple shortest intervals is considered.

Rate of convergence: as an estimator of location of a unimodal distribution, under regularity conditions, the quantity computed here has an asymptotic rate of only \(n^{-1/3}\) and a complicated limiting distribution.

See half.range.mode for an iterative version that refines the estimate iteratively and has a builtin bootstrapping option.

Value

The mean of the x values that lie in the shorth.

Author(s)

Wolfgang Huber http://www.ebi.ac.uk/huber, Ligia Pedroso Bras

half.range.mode

Examples

```r
x = c(rnorm(500), runif(500) * 10)
meth = c("mean", "median", "shorth", "half.range.mode")
est = sapply(meth, function(m) get(m)(x))

if(interactive()) {
  colors = 1:4
  hist(x, 40, col="orange")
  abline(v=est, col=colors, lwd=3, lty=1:2)
  legend(5, 100, names(est), col=colors, lwd=3, lty=1:2)
}
```
**tdata**  
*A small test dataset of Affymetrix Expression data.*

**Description**

The `tdata` data frame has 500 rows and 26 columns. The columns correspond to samples while the rows correspond to genes. The row names are Affymetrix accession numbers.

**Usage**

```r
data(tdata)
```

**Format**

This data frame contains 26 columns.

**Source**

An unknown data set.

**Examples**

```r
data(tdata)
```

**ttest**  
*A filter function for a t.test*

**Description**

`ttest` returns a function of one argument with bindings for `cov` and `p`. The function, when evaluated, performs a t-test using `cov` as the covariate. It returns `TRUE` if the `p` value for a difference in means is less than `p`.

**Usage**

```r
ttest(m, p=0.05, na.rm=TRUE)
```

**Arguments**

- `m`  
  If `m` is of length one then it is assumed that elements one through `m` of `x` will be one group. Otherwise `m` is presumed to be the same length as `x` and constitutes the groups.

- `p`  
  The `p`-value for the test.

- `na.rm`  
  If set to `TRUE` any NA's will be removed.
Details

When the data can be split into two groups (diseased and normal for example) then we often want to select genes on their ability to distinguish those two groups. The t-test is well suited to this and can be used as a filter function.

This helper function creates a t-test (function) for the specified covariate and considers a gene to have passed the filter if the p-value for the gene is less than the prespecified p.

Value

ttest returns a function with bindings for m and p that will perform a t-test.
