Package ‘mixOmics’

May 25, 2024

Type Package

Title Omics Data Integration Project

Version 6.28.0

Depends R (>= 3.5.0), MASS, lattice, ggplot2

Imports igraph, ellipse, corpcor, RColorBrewer, parallel, dplyr, tidyr, reshape2, methods, matrixStats, rARPACK, gridExtra, grDevices, graphics, stats, ggrepel, BiocParallel, utils

Suggests BiocStyle, knitr, rmarkdown, testthat, rgl

Maintainer Max Bladen <mbladen19@gmail.com>

Description Multivariate methods are well suited to large omics data sets where the number of variables (e.g. genes, proteins, metabolites) is much larger than the number of samples (patients, cells, mice). They have the appealing properties of reducing the dimension of the data by using instrumental variables (components), which are defined as combinations of all variables. Those components are then used to produce useful graphical outputs that enable better understanding of the relationships and correlation structures between the different data sets that are integrated. mixOmics offers a wide range of multivariate methods for the exploration and integration of biological datasets with a particular focus on variable selection. The package proposes several sparse multivariate models we have developed to identify the key variables that are highly correlated, and/or explain the biological outcome of interest. The data that can be analysed with mixOmics may come from high throughput sequencing technologies, such as omics data (transcriptomics, metabolomics, proteomics, metagenomics etc) but also beyond the realm of omics (e.g. spectral imaging). The methods implemented in mixOmics can also handle missing values without having to delete entire rows with missing data. A non exhaustive list of methods include variants of generalised Canonical Correlation Analysis, sparse Partial Least Squares and sparse Discriminant Analysis. Recently we implemented integrative methods to combine multiple data sets: N-integration with variants of Generalised Canonical Correlation Analysis and P-integration with variants of multi-group Partial Least Squares.

**auroc**

*Area Under the Curve (AUC) and Receiver Operating Characteristic (ROC) curves for supervised classification*

---

**Description**

Calculates the AUC and plots ROC for supervised models from s/plsda, mint.s/plsda and block.plsda, block.splsda or wrapper.sgccda functions.

**Usage**

```r
auroc(object, ...)  
```

### S3 method for class 'mixo_plsda'

```r
auroc(
  object,
  newdata = object$input.X,
  outcome.test = as.factor(object$Y),
  multilevel = NULL,
  plot = TRUE,
  roc.comp = NULL,
  title = NULL,
  print = TRUE,
  ...
)
```

### S3 method for class 'mixo_splsda'

```r
auroc(
  object,
  newdata = object$input.X,
  outcome.test = as.factor(object$Y),
  multilevel = NULL,
  plot = TRUE,
  roc.comp = NULL,
  title = NULL,
  print = TRUE,
  ...
)
```

### S3 method for class 'list'

```r
auroc(object, plot = TRUE, roc.comp = NULL, title = NULL, print = TRUE, ...)
```
## S3 method for class 'mint.plsda'
auroc(
  object,
  newdata = object$X,
  outcome.test = as.factor(object$Y),
  study.test = object$study,
  multilevel = NULL,
  plot = TRUE,
  roc.comp = NULL,
  roc.study = "global",
  title = NULL,
  print = TRUE,
  ...
)

## S3 method for class 'mint.splsda'
auroc(
  object,
  newdata = object$X,
  outcome.test = as.factor(object$Y),
  study.test = object$study,
  multilevel = NULL,
  plot = TRUE,
  roc.comp = NULL,
  roc.study = "global",
  title = NULL,
  print = TRUE,
  ...
)

## S3 method for class 'sgccda'
auroc(
  object,
  newdata = object$X,
  outcome.test = as.factor(object$Y),
  multilevel = NULL,
  plot = TRUE,
  roc.block = 1L,
  roc.comp = NULL,
  title = NULL,
  print = TRUE,
  ...
)

## S3 method for class 'mint.block.plsda'
auroc(
  object,
  newdata = object$X,
study.test = object$study,
outcome.test = as.factor(object$Y),
multilevel = NULL,
plot = TRUE,
roc.block = 1,
roc.comp = NULL,
title = NULL,
print = TRUE,
...
)

## S3 method for class 'mint.block.splsdasplslsa'
auroc(
  object,
  newdata = object$X,
  study.test = object$study,
  outcome.test = as.factor(object$Y),
multilevel = NULL,
  plot = TRUE,
  roc.block = 1,
  roc.comp = NULL,
  title = NULL,
  print = TRUE,
  ...
)

Arguments

object Object of class inherited from one of the following supervised analysis function: "plsda", "splsda", "mint.plsda", "mint.splsda", "block.splsda" or "wrapper.sgccda". Alternatively, this can be a named list of plsda and splsda objects if multiple models are to be compared. Note that these multiple models need to have used the same levels in the response variable.

... external optional arguments for plotting - line.col for custom colors and legend.title for custom legend title

newdata numeric matrix of predictors, by default set to the training data set (see details).

outcome.test Either a factor or a class vector for the discrete outcome, by default set to the outcome vector from the training set (see details).

multilevel Sample information when a newdata matrix is input and when multilevel decomposition for repeated measurements is required. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples in splsda.

plot Whether the ROC curves should be plotted, by default set to TRUE (see details).

roc.comp Specify the component (integer) up to which the ROC will be calculated and plotted from the multivariate model, default to 1.

title Character, specifies the title of the plot.
print Logical, specifies whether the output should be printed.

study.test For MINT objects, grouping factor indicating which samples of newdata are from the same study. Overlap with object$study are allowed.

roc.study Specify the study for which the ROC will be plotted for a mint.plsda or mint.splsda object, default to "global".

roc.block Specify the block number (integer) or the name of the block (set of characters) for which the ROC will be plotted for a block.plsda or block.splsda object, default to 1.

Details

For more than two classes in the categorical outcome Y, the AUC is calculated as one class vs. the other and the ROC curves one class vs. the others are output.

The ROC and AUC are calculated based on the predicted scores obtained from the predict function applied to the multivariate methods (predict(object)$predict). Our multivariate supervised methods already use a prediction threshold based on distances (see predict) that optimally determine class membership of the samples tested. As such AUC and ROC are not needed to estimate the performance of the model (see perf, tune that report classification error rates). We provide those outputs as complementary performance measures.

The pvalue is from a Wilcoxon test between the predicted scores between one class vs the others.

External independent data set (newdata) and outcome (outcome.test) can be input to calculate AUROC. The external data set must have the same variables as the training data set (object$X).

If object is a named list of multiple plsda and splsda objects, ensure that these models each have a response variable with the same levels. Additionally, newdata and outcome.test cannot be passed to this form of auroc.

If newdata is not provided, AUROC is calculated from the training data set, and may result in overfitting (too optimistic results).

Note that for mint.plsda and mint.splsda objects, if roc.study is different from "global", then newdata), outcome.test and study.test are not used.

Value

Depending on the type of object used, a list that contains: The AUC and Wilcoxon test pvalue for each 'one vs other' classes comparison performed, either per component (splsda, plsda, mint.plsda, mint.splsda), or per block and per component (wrapper.sgccda, block.plsda, block.splsda).

Examples

## example with PLSDA, 2 classes
# ----------------
data(breast.tumors)
X <- breast.tumors$gene.exp
Y <- breast.tumors$sample$treatment

plsda.breast <- plsda(X, Y, ncomp = 2)
auc.plsda.breast = auroc(plsda.breast, roc.comp = 1)
auc.plsda.breast = auroc(plsda.breast, roc.comp = 2)

## Not run:
## example with sPLSDA
# -----------------
splsda.breast <- splsda(X, Y, ncomp = 2, keepX = c(25, 25))
auroc(plsda.breast, plot = FALSE)

## example with sPLSDA with 4 classes
# -----------------
data(liver.toxicity)
X <- as.matrix(liver.toxicity$gene)
# Y will be transformed as a factor in the function,
# but we set it as a factor to setup the colors.
Y <- as.factor(liver.toxicity$treatment[,4])
splsda.liver <- splsda(X, Y, ncomp = 2, keepX = c(20, 20))
auc.splsda.liver = auroc(splsda.liver, roc.comp = 2)

## example with mint.plsda
# -----------------
data(stemcells)
res = mint.plsda(X = stemcells$gene, Y = stemcells$celltype, ncomp = 3,
study = stemcells$study)
auc.mint.plsda = auroc(res, plot = FALSE)

## example with mint.splsda
# -----------------
res = mint.splsda(X = stemcells$gene, Y = stemcells$celltype, ncomp = 3, keepX = c(10, 5, 15),
study = stemcells$study)
auc.mint.splsda = auroc(res, plot = TRUE, roc.comp = 3)

## example with block.plsda
# ------------------
data(nutrimouse)
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid)
# with this design, all blocks are connected
design = matrix(c(0,1,1,0), ncol = 2, nrow = 2,
byrow = TRUE, dimnames = list(names(data), names(data)))
block.plsda.nutri = block.plsda(X = data, Y = nutrimouse$diet)
auc.block.plsda.nutri = auroc(block.plsda.nutri, roc.block = 'lipid')

## example with block.splsda
# ---------------
list.keepX = list(gene = rep(10, 2), lipid = rep(5,2))
block.splsda.nutri = block.splsda(X = data, Y = nutrimouse$diet, keepX = list.keepX)
auc.block.splsda.nutri = auroc(block.splsda.nutri, roc.block = 1)

## End(Not run)

---

**background.predict**  
*Calculate prediction areas*

**Description**

Calculate prediction areas that can be used in plotIndiv to shade the background.

**Usage**

```r
background.predict(
  object,
  comp.predicted = 1,
  dist = "max.dist",
  xlim = NULL,
  ylim = NULL,
  resolution = 100
)
```

**Arguments**

- **object**
  A list of data sets (called 'blocks') measured on the same samples. Data in
  the list should be arranged in matrices, samples x variables, with samples order
  matching in all data sets.

- **comp.predicted**
  Matrix response for a multivariate regression framework. Data should be contin-
  uous variables (see block.splsda for supervised classification and factor reponse).

- **dist**
  distance to use to predict the class of new data, should be a subset of "centroids.dist",
  "mahalanobis.dist" or "max.dist" (see predict).

- **xlim, ylim**
  numeric list of vectors of length 2, giving the x and y coordinates ranges for the
  simulated data. By default will be 1.2* the range of object$variates$X[i]

- **resolution**
  A total of resolution*resolution data are simulated between xlim[1], xlim[2],
  ylim[1] and ylim[2].
**Details**

`background.predict` simulates `resolution*resolution` points within the rectangle defined by `xlim` on the x-axis and `ylim` on the y-axis, and then predicts the class of each point (defined by two coordinates). The algorithm estimates the predicted area for each class, defined as the 2D surface where all points are predicted to be of the same class. A polygon is returned and should be passed to `plotIndiv` for plotting the actual background.

Note that by default `xlim` and `ylim` will create a rectangle of simulated data that will cover the plotted area of `plotIndiv`. However, if you use `plotIndiv` with `ellipse=TRUE` or if you set `xlim` and `ylim`, then you will need to adapt `xlim` and `ylim` in `background.predict`.

Also note that the white frontier that defines the predicted areas when plotting with `plotIndiv` can be reduced by increasing `resolution`.

More details about the prediction distances in `?predict` and the supplemental material of the `mixOmics` article (Rohart et al. 2017).

**Value**

`background.predict` returns a list of coordinates to be used with `polygon` to draw the predicted area for each class.

**Author(s)**

Florian Rohart, Al J Abadi

**References**

**See Also**

`plotIndiv`, `predict`, `polygon`.

**Examples**

```r
# Example 1
# -----------------------------------
data(breast.tumors)
X <- breast.tumors$gene.exp
Y <- breast.tumors$sample$treatment

splsda.breast <- splsda(X, Y,keepX=c(10,10),ncomp=2)

# calculating background for the two first components, and the centroids distance
background = background.predict(splsda.breast, comp.predicted = 2, dist = "centroids.dist")

## Not run:
# default option: note that the outcome color is included by default!
plotIndiv(splsda.breast, background = background, legend=TRUE)
```
# Example 2
# -----------------------------------
data(liver.toxicity)
X = liver.toxicity$gene
Y = as.factor(liver.toxicity$treatment[, 4])

plsda.liver <- plsda(X, Y, ncomp = 2)

# calculating background for the two first components, and the mahalanobis distance
background = background.predict(plsda.liver, comp.predicted = 2, dist = "mahalanobis.dist")

plotIndiv(plsda.liver, background = background, legend = TRUE)

## End(Not run)

---

**biplot**  

**biplot methods for pca family**

**Description**

biplot methods for pca family

**Usage**

```r
## S3 method for class 'pca'
biplot(
  x,
  comp = c(1, 2),
  block = NULL,
  ind.names = TRUE,
  group = NULL,
  cutoff = 0,
  col.per.group = NULL,
  col = NULL,
  ind.names.size = 3,
  ind.names.col = color.mixo(4),
  ind.names.repel = TRUE,
  pch = 19,
  pch.levels = NULL,
  pch.size = 2,
  var.names = TRUE,
  var.names.col = "grey40",
  var.names.size = 4,
  var.names.angle = FALSE,
)```
biplot

var.arrow.col = "grey40",
var.arrow.size = 0.5,
var.arrow.length = 0.2,
ind.legend.title = NULL,
vline = FALSE,
hline = FALSE,
legend = if (is.null(group)) FALSE else TRUE,
legend.title = NULL,
pch.legend.title = NULL,
cex = 1.05,
...
)

## S3 method for class 'mixo_pls'
biplot(
  x,
  comp = c(1, 2),
  block = NULL,
  ind.names = TRUE,
  group = NULL,
cutoff = 0,
col.per.group = NULL,
col = NULL,
ind.names.size = 3,
ind.names.col = color.mixo(4),
ind.names.repel = TRUE,
pch = 19,
pch.levels = NULL,
pch.size = 2,
var.names = TRUE,
var.names.col = "grey40",
var.names.size = 4,
var.names.angle = FALSE,
var.arrow.col = "grey40",
var.arrow.size = 0.5,
var.arrow.length = 0.2,
ind.legend.title = NULL,
vline = FALSE,
hline = FALSE,
legend = if (is.null(group)) FALSE else TRUE,
legend.title = NULL,
pch.legend.title = NULL,
cex = 1.05,
...
)

Arguments

x An object of class 'pca' or mixOmics '(s)pls'.
biplot

comp
- integer vector of length two (or three to 3d). The components that will be used on the horizontal and the vertical axis respectively to project the individuals.

block
- Character, name of the block to show for pls object. Default to ’X’.

ind.names
- either a character vector of names for the individuals to be plotted, or FALSE for no names. If TRUE, the row names of the first (or second) data matrix is used as names (see Details).

group
- Factor indicating the group membership for each sample.

cutoff
- numeric between 0 and 1. Variables with correlations below this cutoff in absolute value are not plotted (see Details).

col.per.group
- character (or symbol) color to be used when ’group’ is defined. Vector of the same length as the number of groups.

col
- character (or symbol) color to be used, possibly vector.

ind.names.size
- Numeric, sample name size.

ind.names.col
- Character, sample name colour.

ind.names.repel
- Logical, whether to repel away label names.

pch
- plot character. A character string or a vector of single characters or integers. See points for all alternatives.

pch.levels
- If pch is a factor, a named vector providing the point characters to use. See examples.

pch.size
- Numeric, sample point character size.

var.names
- Logical indicating whether to show variable names. Alternatively, a character.

var.names.col
- Character, variable name colour.

var.names.size
- Numeric, variable name size.

var.names.angle
- Logical, whether to align variable names to arrow directions.

var.arrow.col
- Character, variable arrow colour. If ’NULL’, no arrows are shown.

var.arrow.size
- Numeric, variable arrow head size.

var.arrow.length
- Numeric, length of the arrow head in ’cm’.

ind.legend.title
- Character, title of the legend.

vline
- Logical, whether to draw the vertical neutral line.

hline
- Logical, whether to draw the horizontal neutral line.

legend
- Logical, whether to show the legend if group != NULL.

legend.title
- Character, the legend title if group != NULL.

pch.legend.title
- Character, the legend title if pch is a factor.

cex
- Numeric scalar indicating the desired magnification of plot texts. theme function may be used with the output object if further customisation is required.

... Not currently used.

pch.legend
- Character, the legend title if pch is a factor.
Details

`biplot` unifies the reduced representation of both the observations/samples and variables of a matrix of multivariate data on the same plot. Essentially, in the reduced space the samples are shown as points/names and the contributions of features to each dimension are shown as directed arrows or vectors. For PLS objects it is possible to use either 'X' or 'Y' latent space using `block` argument.

Value

A ggplot object.

Author(s)

Al J Abadi

Examples

data("nutrimouse")

## --------- pca ---------- ##
pca.lipid <- pca(nutrimouse$lipid, ncomp = 3, scale = TRUE)
# seed for reproducible geom_text_repel
set.seed(42)
biplot(pca.lipid)

## correlation cutoff to filter features
biplot(pca.lipid, cutoff = c(0.8))

## tailor threshold for each component
biplot(pca.lipid, cutoff = c(0.8, 0.7))

## customise components
biplot(pca.lipid, cutoff = c(0.8), comp = c(1,3))

## customise ggplot in an arbitrary way
biplot(pca.lipid) + theme_linedraw() +
  # add vline
  geom_vline(xintercept = 0, col = 'green') +
  # add hline
  geom_hline(yintercept = 0, col = 'green') +
  # customise labs
  labs(x = 'Principal Component 1', y = 'Principal Component 2')

## group samples
biplot(pca.lipid, group = nutrimouse$diet, legend.title = 'Diet')

## customise variable labels
biplot(pca.lipid,
  var.names.col = color.mixo(2),
  var.names.size = 4,
  var.names.angle = TRUE)

## no arrows
biplot(pca.lipid, group = nutrimouse$diet, legend.title = 'Diet',
  var.arrow.col = NULL, var.names.col = 'black')
## add x=0 and y=0 lines in function
biplot(pca.lipid, group = nutrimouse$diet, legend.title = 'Diet',
       var.arrow.col = NULL, var.names.col = 'black',
       vline = TRUE, hline = TRUE)

## --------- spca
## example with spca
spca.lipid <- spca(nutrimouse$lipid, ncomp = 2, scale = TRUE, keepX = c(8, 6))
biplot(spca.lipid, var.names.col = 'black', group = nutrimouse$diet,
       legend.title = 'Diet')

## --------- pls ---------- ##
data("nutrimouse")
pls.nutrimouse <- pls(X = nutrimouse$gene, Y = nutrimouse$lipid, ncomp = 2)
biplot(pls.nutrimouse, group = nutrimouse$genotype, block = 'X',
       legend.title = 'Genotype', cutoff = 0.878)
biplot(pls.nutrimouse, group = nutrimouse$genotype, block = 'Y',
       legend.title = 'Genotype', cutoff = 0.8)

## --------- plsda ---------- ##
data(breast.tumors)

**block.pls**

*N-integration with Projection to Latent Structures models (PLS)*

### Description
Integration of multiple data sets measured on the same samples or observations, ie. N-integration. The method is partly based on Generalised Canonical Correlation Analysis.

### Usage
```r
block.pls(
  X,
  Y,
  indY,
  ncomp = 2,
  design,
  scheme,
```
mode,  
scale = TRUE,  
init,  
tol = 1e-06,  
max.iter = 100,  
near.zero.var = FALSE,  
all.outputs = TRUE,  
verbose.call = FALSE  
)  

Arguments

X A named list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.

Y Matrix response for a multivariate regression framework. Data should be continuous variables (see ?block.plsda for supervised classification and factor response).

indY To supply if Y is missing, indicates the position of the matrix response in the list X.

ncomp the number of components to include in the model. Default to 2. Applies to all blocks.

design numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c('null', 'full') indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.

scheme Character, one of 'horst', 'factorial' or 'centroid'. Default = 'horst', see reference.

mode Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

init Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y (‘svd’) or each block independently (‘svd.single’). Default = svd.single

tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter Integer, the maximum number of iterations. Default to 100.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.
Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

block.pls function fits a horizontal integration PLS model with a specified number of components per block. An outcome needs to be provided, either by Y or by its position indY in the list of blocks X. Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the impute.nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).

Note that our method is partly based on Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, J Chemom 3(1) and Westerhuis et al., 1998, J Chemom, 12(5).

Value

block.pls returns an object of class 'block.pls', a list that contains the following components:

- X the centered and standardized original predictor matrix.
- indY the position of the outcome Y in the output list X.
- ncomp the number of components included in the model for each block.
- mode the algorithm used to fit the model.
- variates list containing the variates of each block of X.
- loadings list containing the estimated loadings for the variates.
- names list containing the names to be used for individuals and variables.
- nzv list containing the zero- or near-zero predictors information.
- iter Number of iterations of the algorithm for each component
- prop_expl_var Percentage of explained variance for each component and each block
- call if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessable via this component

**block.plsda**

*N-integration with Projection to Latent Structures models (PLS) with Discriminant Analysis*

**Description**

Integration of multiple data sets measured on the same samples or observations to classify a discrete outcome, i.e. N-integration with Discriminant Analysis. The method is partly based on Generalised Canonical Correlation Analysis.
Usage

```r
block.plsda(
  X,
  Y,
  indY,
  ncomp = 2,
  design,
  scheme,
  scale = TRUE,
  init = "svd",
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)
```

Arguments

- **X**: A named list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
- **Y**: a factor or a class vector for the discrete outcome.
- **indY**: To supply if Y is missing, indicates the position of the matrix response in the list X.
- **ncomp**: the number of components to include in the model. Default to 2. Applies to all blocks.
- **design**: numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c('null', 'full') indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
- **scheme**: Character, one of 'horst', 'factorial' or 'centroid'. Default = 'horst', see reference.
- **scale**: Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE).
- **init**: Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ('svd') or each block independently ('svd.single'). Default = svd.single
- **tol**: Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.
- **max.iter**: Integer, the maximum number of iterations. Default to 100.
near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = FALSE.

verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

block.plsda function fits a horizontal integration PLS-DA model with a specified number of components per block. A factor indicating the discrete outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the impute.nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).

Note that our method is partly based on Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, J Chemom 3(1) and Westerhuis et al., 1998, J Chemom, 12(5).

Value

block.plsda returns an object of class "block.plsda", "block.pls", a list that contains the following components:

- **X** the centered and standardized original predictor matrix.
- **indY** the position of the outcome Y in the output list X.
- **ncomp** the number of components included in the model for each block.
- **mode** the algorithm used to fit the model.
- **variates** list containing the variates of each block of X.
- **loadings** list containing the estimated loadings for the variates.
- **names** list containing the names to be used for individuals and variables.
- **nzv** list containing the zero- or near-zero predictors information.
- **iter** Number of iterations of the algorithm for each component
- **prop_expl_var** Percentage of explained variance for each component and each block
- **call** if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessable via this component

Examples

data(nutrimouse)
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid, Y = nutrimouse$diet)
# with this design, all blocks are connected
design = matrix(c(0,1,1,1,0,1,1,1,0), ncol = 3, nrow = 3, byrow = TRUE, dimnames = list(names(data), names(data)))

res = block.plsda(X = data, indY = 3) # indY indicates where the outcome Y is in the list X
plotIndiv(res, ind.names = FALSE, legend = TRUE)
plotVar(res)

## Not run:
# when Y is provided
res2 = block.plsda(list(gene = nutrimouse$gene, lipid = nutrimouse$lipid),
Y = nutrimouse$diet, ncomp = 2)
plotIndiv(res2)
plotVar(res2)

## End(Not run)
### Description

Integration of multiple data sets measured on the same samples or observations, with variable selection in each data set, ie. N-integration. The method is partly based on Generalised Canonical Correlation Analysis.

### Usage

```r
block.spls(
  X,
  Y,
  indY,
  ncomp = 2,
  keepX,
  keepY,
  design,
  scheme,
  mode,
  scale = TRUE,
  init,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)
```

### Arguments

- **X**: A named list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
- **Y**: Matrix response for a multivariate regression framework. Data should be continuous variables (see ?block.splsda for supervised classification and factor response).
- **indY**: To supply if Y is missing, indicates the position of the matrix response in the list X.
- **ncomp**: the number of components to include in the model. Default to 2. Applies to all blocks.
- **keepX**: A named list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.
keepY Only if Y is provided (and not indY). Each entry is the number of variables to select in each of the blocks of Y for each component.

design numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c('null', 'full') indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.

scheme Character, one of 'horst', 'factorial' or 'centroid'. Default = 'horst', see reference.

mode Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

init Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ('svd') or each block independently ('svd.single'). Default = svd.single

tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter Integer, the maximum number of iterations. Default to 100.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

block.spls function fits a horizontal sPLS model with a specified number of components per block). An outcome needs to be provided, either by Y or by its position indY in the list of blocks X. Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).

Note that our method is partly based on sparse Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, J Chemom 3(1), Westerhuis
Variable selection is performed on each component for each block of X, and for Y if specified, via input parameter keepX and keepY.

Note that if Y is missing and indY is provided, then variable selection on Y is performed by specifying the input parameter directly in keepX (no keepY is needed).

Value

block.spls returns an object of class "block.spls", a list that contains the following components:

- X: the centered and standardized original predictor matrix.
- indY: the position of the outcome Y in the output list X.
- ncomp: the number of components included in the model for each block.
- mode: the algorithm used to fit the model.
- keepX: Number of variables used to build each component of each block
- keepY: Number of variables used to build each component of Y
- variates: list containing the variates of each block of X.
- loadings: list containing the estimated loadings for the variates.
- names: list containing the names to be used for individuals and variables.
- nzv: list containing the zero- or near-zero predictors information.
- iter: Number of iterations of the algorithm for each component
- prop_expl_var: Percentage of explained variance for each component and each block after setting possible missing values in the centered data to zero
- call: if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessible via this component

block.splsdan -integration and feature selection with Projection to Latent Structures models (PLS) with sparse Discriminant Analysis

Description

Integration of multiple data sets measured on the same samples or observations to classify a discrete outcome to classify a discrete outcome and select features from each data set, ie. N-integration with
sparse Discriminant Analysis. The method is partly based on Generalised Canonical Correlation Analysis.

Usage

block.splsda(
  X,
  Y,
  indY,
  ncomp = 2,
  keepX,
  design,
  scheme,
  scale = TRUE,
  init = "svd",
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)

wrapper.sgcca(
  X,
  Y,
  indY,
  ncomp = 2,
  keepX,
  design,
  scheme,
  scale = TRUE,
  init = "svd",
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)

Arguments

X A named list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.

Y a factor or a class vector for the discrete outcome.

indY To supply if Y is missing, indicates the position of the matrix response in the list X.
block.splsda

ncomp  the number of components to include in the model. Default to 2. Applies to all blocks.

keepX  A named list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.

design  numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c('null', 'full') indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.

scheme  Character, one of 'horst', 'factorial' or 'centroid'. Default = 'horst', see reference.

scale  Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

init  Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ('svd') or each block independently ('svd.single'). Default = svd.single

tol  Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter  Integer, the maximum number of iterations. Default to 100.

near.zero.var  Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs  Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call  Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

block.splsda function fits a horizontal integration PLS-DA model with a specified number of components per block). A factor indicating the discrete outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the impute.nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).
Note that our method is partly based on sparse Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, J Chemom 3(1), Westerhuis et al., 1998, J Chemom, 12(5) and sparse variants Li et al., 2012, Bioinformatics 28(19); Karaman et al (2014), Metabolomics, 11(2); Kawaguchi et al., 2017, Biostatistics.

Variable selection is performed on each component for each block of $X$ if specified, via input parameter `keepX`.

**Value**

`block.splsda` returns an object of class "block.splsda", "block.pls", a list that contains the following components:

- **$X$** the centered and standardized original predictor matrix.
- **indY** the position of the outcome $Y$ in the output list $X$.
- **ncomp** the number of components included in the model for each block.
- **mode** the algorithm used to fit the model.
- **keepX** Number of variables used to build each component of each block
- **variates** list containing the variates of each block of $X$.
- **loadings** list containing the estimated loadings for the variates.
- **names** list containing the names to be used for individuals and variables.
- **nzv** list containing the zero- or near-zero predictors information.
- **iter** Number of iterations of the algorithm for each component
- **weights** Correlation between the variate of each block and the variate of the outcome. Used to weight predictions.
- **prop_expl_var** Percentage of explained variance for each component and each block
- **call** if `verbose.call = FALSE`, then just the function call is returned. If `verbose.call = TRUE` then all the inputted values are accessible via this component

---

**breast.TCGA**

**Breast Cancer multi omics data from TCGA**

**Description**

This data set is a small subset of the full data set from The Cancer Genome Atlas that can be analysed with the DIABLO framework. It contains the expression or abundance of three matching omics data sets: mRNA, miRNA and proteomics for 150 breast cancer samples (Basal, Her2, Luminal A) in the training set, and 70 samples in the test set. The test set is missing the proteomics data set.

**Usage**

```r
data(breast.TCGA)
```

**Format**

A list containing two data sets, `data.train` and `data.test` which both include:

- `list("miRNA")` data frame with 150 (70) rows and 184 columns in the training (test) data set. The expression levels of 184 miRNA.
- `list("mRNA")` data frame with 150 (70) rows and 520 columns in the training (test) data set. The expression levels of 200 mRNA.
- `list("protein")` data frame with 150 (70) rows and 142 columns in the training data set only. The abundance of 142 proteins.
- `list("subtype")` a factor indicating the breast cancer subtypes in the training (length of 150) and test (length of 70) sets.

**Details**

The data come from The Cancer Genome Atlas (TCGA, http://cancergenome.nih.gov/). We divided the data into a training (discovery) and test (validation) set. The protein dataset which had a limited number of subjects available was used to allocate subjects into the training set only, while the test set included all remaining subject. Each data set was normalised and pre-processed. For illustrative purposes we drastically filtered the data here.
Value

none

Source

The raw data were downloaded from http://cancergenome.nih.gov/. The normalised and filtered data we analysed with DIABLO are available on www.mixOmics.org/mixDIABLO

breast.tumors  Human Breast Tumors Data

Description

This data set contains the expression of 1,000 genes in 47 surgical specimens of human breast tumours from 17 different individuals before and after chemotherapy treatment.

Usage

data(breast.tumors)

Format

A list containing the following components:

- list("gene.exp")  data matrix with 47 rows and 1000 columns. Each row represents an experimental sample, and each column a single gene.
- list("sample")  a list containing two character vector components: name the name of the samples, and treatment the treatment status.
- list("genes")  a list containing two character vector components: name the name of the genes, and description the description of each gene.

Details

This data consists of 47 breast cancer samples and 1753 cDNA clones pre-selected by Perez-Enciso et al. (2003) to draw their Fig. 1. The authors selected 47 samples for which there was information at least before or before and after chemotherapy treatment. There were 20 tumours that were microarrayed both before and after treatment. For illustrative purposes we then randomly selected 1000 cDNA clones for this data set.

Value

none
The Human Breast Tumors dataset is a companion resource for the paper of Perou et al. (2000), and was downloaded from the Stanford Genomics Breast Cancer Consortium Portal http://genome-www.stanford.edu/breast_cancer/molecularportraits/download.shtml.

cim

Clustered Image Maps (CIMs) ("heat maps")

Description

This function generates color-coded Clustered Image Maps (CIMs) ("heat maps") to represent "high-dimensional" data sets.

Usage

cim(
  mat = NULL,
  color = NULL,
  row.names = TRUE,
  col.names = TRUE,
  row.sideColors = NULL,
  col.sideColors = NULL,
  row.cex = NULL,
  col.cex = NULL,
  cutoff = 0,
  cluster = "both",
  dist.method = c("euclidean", "euclidean"),
  clust.method = c("complete", "complete"),
  cut.tree = c(0, 0),
  transpose = FALSE,
  symkey = TRUE,
  keysize = c(1, 1),
  keysize.label = 1,
  zoom = FALSE,
  title = NULL,
  xlab = NULL,
  ylab = NULL,
)
margins = c(5, 5),
lhei = NULL,
lwid = NULL,
comp = NULL,
center = TRUE,
scale = FALSE,
legend = NULL,
save = NULL,
name.save = NULL,
blocks = NULL)
)

Arguments

mat numeric matrix of values to be plotted. Alternatively, an object of class inher-
iting from "pca", "spca", "ipca", "sipca", "rcc", "pls", "spls", "plsta", 
"splstda", "mlspls", "mlsplsda", "block.pls" or "block.spls" (where "ml" 
stands for multilevel).

color a character vector of colors such as that generated by terrain.colors, topo.colors, 
rainbow, color.jet or similar functions.

row.names, col.names logical, should the name of rows and/or columns of mat be shown? If TRUE 
(defaults) rownames(mat) and/or colnames(mat) are used. Possible character 
vectors with row and/or column labels can be used.

row.sideColors (optional) character vector of length nrow(mat) containing the color names for 
a vertical side bar that may be used to annotate the rows of mat.

col.sideColors (optional) character vector of length ncol(mat) containing the color names for 
a horizontal side bar that may be used to annotate the columns of mat.

row.cex, col.cex positive numbers, used as cex.axis in for the row or column axis labeling. The 
defaults currently only use number of rows or columns, respectively.

cutoff numeric between 0 and 1. Variables with correlations below this threshold in 
absolute value are not plotted. To use only when mapping is "XY".

cluster character string indicating whether to cluster "none", "row", "column" or "both". 
Defaults to "both".

dist.method character vector of length two. The distance measure used in clustering rows 
and columns. Possible values are "correlation" for Pearson correlation and 
all the distances supported by dist, such as "euclidean", etc.

clust.method character vector of length two. The agglomeration method to be used for rows 
and columns. Accepts the same values as in hclust such as "ward", "complete", 
etc.

cut.tree numeric vector of length two with components in [0,1]. The height proportions 
where the trees should be cut for rows and columns, if these are clustered.

transpose logical indicating if the matrix should be transposed for plotting. Defaults to 
FALSE.
symkey Logical indicating whether the color key should be made symmetric about 0. Defaults to TRUE.

keysize vector of length two, indicating the size of the color key.

keysize.label vector of length 1, indicating the size of the labels and title of the color key.

zoom logical. Whether to use zoom for interactive zoom. See Details.

title, xlab, ylab title, x- and y-axis titles; default to none.

margins numeric vector of length two containing the margins (see par(mar)) for column and row names respectively.

lhei, lwid arguments passed to layout to divide the device up into two (or three if a side color is drawn) rows and two columns, with the row-heights lhei and the column-widths lwid.

comp atomic or vector of positive integers. The components to adequately account for the data association. For a non sparse method, the similarity matrix is computed based on the variates and loading vectors of those specified components. For a sparse approach, the similarity matrix is computed based on the variables selected on those specified components. See example. Defaults to comp = 1:object$ncomp.

center either a logical value or a numeric vector of length equal to the number of columns of mat. See scale function.

scale either a logical value or a numeric vector of length equal to the number of columns of mat. See scale function.

mapping character string indicating whether to map "X", "Y" or "XY"-association matrix. Can also be "multiblock" when class(mat) == "block.pls" OR "block.spls". See Details.

legend A list indicating the legend for each group, the color vector, title of the legend and cex.

save should the plot be saved? If so, argument to be set to either 'jpeg', 'tiff', 'png' or 'pdf'.

name.save character string for the name of the file to be saved.

blocks integer or character vector. Used when class(mat) == "block.pls" OR "block.spls". Dictates which blocks will be visualised. See Details.

## Details

One matrix Clustered Image Map (default method) is a 2-dimensional visualization of a real-valued matrix (basically image(t(mat))) with rows and/or columns reordered according to some hierarchical clustering method to identify interesting patterns. Generated dendrograms from clustering are added to the left side and to the top of the image. By default the used clustering method for rows and columns is the complete linkage method and the used distance measure is the distance euclidean.

In "pca", "spca", "ipca", "sipca", "plsda", "splsda" and multilevel variants methods the mat matrix is object$X.

For the remaining methods, if mapping = "X" or mapping = "Y" the mat matrix is object$X or object$Y respectively. If mapping = "XY":

...
in rcc method, the matrix mat is created where element \((j, k)\) is the scalar product value between every pairs of vectors in dimension \(\text{length(comp)}\) representing the variables \(X_j\) and \(Y_k\) on the axis defined by \(Z_i\) with \(i\) in comp, where \(Z_i\) is the equiangular vector between the \(i\)-th \(X\) and \(Y\) canonical variate.

in pls, spls and multilevel spls methods, if object$mode is "regression", the element \((j, k)\) of the matrix mat is given by the scalar product value between every pairs of vectors in dimension \(\text{length(comp)}\) representing the variables \(X_j\) and \(Y_k\) on the axis defined by \(U_i\) with \(i\) in comp, where \(U_i\) is the \(i\)-th \(X\) variate. If object$mode is "canonical" then \(X_j\) and \(Y_k\) are represented on the axis defined by \(U_i\) and \(V_i\) respectively.

The blocks parameter controls which blocks are to be included when class(mat) == "block.pls" OR "block.spls". This can be a character or a integer vector.

If using a multiblock object then mapping can be set to "multiblock". When done so, this will emulate the function of cimDiablo(), such that rows will denote each sample and all features included in blocks will be shown as columns, coloured by which block they inherit from. In this case, blocks can include any number of input blocks. If mapping = "X", "Y" OR "XY", then it functions similarly to if a mixo_pls object was being used. blocks has to be of length 2 in this scenario.

By default four components will be displayed in the plot. At the top left is the color key, top right is the column dendogram, bottom left is the row dendogram, bottom right is the image plot. When sideColors are provided, an additional row or column is inserted in the appropriate location. This layout can be overriden by specifying appropriate values for \(\text{lwid}\) and \(\text{lhei}\). \(\text{lwid}\) controls the column width, and \(\text{lhei}\) controls the row height. See the help page for layout for details on how to use these arguments.

For visualization of "high-dimensional" data sets, a nice zooming tool was created. zoom = TRUE open a new device, one for CIM, one for zoom-out region and define an interactive 'zoom' process: click two points at imagen map region by pressing the first mouse button. It then draws a rectangle around the selected region and zoom-out this at new device. The process can be repeated to zoom-out other regions of interest.

The zoom process is terminated by clicking the second button and selecting 'Stop' from the menu, or from the 'Stop' menu on the graphics window.

Value

A list containing the following components:

- **M** the mapped matrix used by cim.
- **rowInd, colInd** row and column index permutation vectors as returned by order.dendrogram.
- **ddr, ddc** object of class "dendrogram" which describes the row and column trees produced by cim.
- **mat.cor** the correlation matrix used for the heatmap. Available only when mapping = "XY".
- **row.names, col.names** character vectors with row and column labels used.
- **row.sideColors, col.sideColors** character vector containing the color names for vertical and horizontal side bars used to annotate the rows and columns.

cimDiablo

Clustered Image Maps (CIMs) ("heat maps") for DIABLO

Description

This function generates color-coded Clustered Image Maps (CIMs) ("heat maps") to represent "high-dimensional" data sets analysed with DIABLO.

Usage

cimDiablo(
  object,
  color = NULL,
  color.Y,
  color.blocks,
  comp = NULL,
  margins = c(2, 15),
  legend.position = "topright",
  transpose = FALSE,
  row.names = TRUE,
  col.names = TRUE,
  size.legend = 1.5,
  trim = TRUE,
  ...
)

Arguments

object An object of class inheriting from "block.splsda".
color A character vector of colors such as that generated by terrain.colors, topo.colors, rainbow, color.jet or similar functions.
color.Y A character vector of colors to be used for the levels of the outcome
color.blocks A character vector of colors to be used for the blocks
comp A positive integer. The similarity matrix is computed based on the variables selected on those specified components. See example. Defaults to comp = 1.
margins numeric vector of length two containing the margins (see \texttt{par(mar)}) for column and row names respectively.

\texttt{legend.position}
position of the legend, one of "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center".

\texttt{transpose}
logical indicating if the matrix should be transposed for plotting. Defaults to \texttt{FALSE}.

\texttt{row.names, col.names}
logical, should the name of rows and/or columns of \texttt{mat} be shown? If \texttt{TRUE} (defaults) \texttt{rownames(mat)} and/or \texttt{colnames(mat)} are used. Possible character vectors with row and/or column labels can be used.

\texttt{size.legend}
size of the legend

\texttt{trim}
(Logical or numeric) If \texttt{FALSE}, values are not changed. If \texttt{TRUE}, the values are trimmed to 3 standard deviation range. If a numeric, values with absolute values greater than the provided values are trimmed.

\texttt{...}
Other valid arguments passed to \texttt{cim}.

\textbf{Details}

This function is a small wrapper of \texttt{cim} specific to the DIABLO framework.

\textbf{Value}

A list containing the following components:

\texttt{M}
the mapped matrix used by \texttt{cim}.

\texttt{rowInd, colInd}
row and column index permutation vectors as returned by \texttt{order.dendrogram}.

\texttt{ddr, ddc}
object of class "dendrogram" which describes the row and column trees produced by \texttt{cim}.

\texttt{mat.cor}
the correlation matrix used for the heatmap. Available only when mapping = "XY".

\texttt{row.names, col.names}
character vectors with row and column labels used.

\texttt{row.sideColors, col.sideColors}
character vector containing the color names for vertical and horizontal side bars used to annotate the rows and columns.

circosPlot

### circosPlot for DIABLO

**Description**

Displays variable correlation among different blocks
Usage

## S3 method for class 'block.splsda'
circosPlot(
  object,
  comp = 1:min(object$ncomp),
  cutoff,
  color.Y,
  blocks = NULL,
  color.blocks,
  color.cor,
  var.names = NULL,
  showIntraLinks = FALSE,
  line = FALSE,
  size.legend = 0.8,
  ncol.legend = 1,
  size.variables = 0.25,
  size.labels = 1,
  legend = TRUE,
  legend.title = "Expression",
  linkWidth = 1,
  ...
)

## S3 method for class 'block.plsda'
circosPlot(
  object,
  comp = 1:min(object$ncomp),
  cutoff,
  color.Y,
  blocks = NULL,
  color.blocks,
  color.cor,
  var.names = NULL,
  showIntraLinks = FALSE,
  line = FALSE,
  size.legend = 0.8,
  ncol.legend = 1,
  size.variables = 0.25,
  size.labels = 1,
  legend = TRUE,
  legend.title = "Expression",
  linkWidth = 1,
  ...
)

## S3 method for class 'block.spls'
circosPlot(object, ..., group = NULL, Y.name = "Y")
## S3 method for class 'block.pls'
circosPlot(object, ..., group = NULL, Y.name = "Y")

### Arguments

- **object**: An object of class inheriting from "block.plsda", "block.splsda", "block.pls" or "blocks.spls".
- **comp**: Numeric vector indicating which component to plot. Default to all.
- **cutoff**: Only shows links with a correlation higher than cutoff.
- **color.Y**: a character vector of colors to be used for the levels of the outcome.
- **blocks**: Character or integer vector indicating which blocks to show. Default to all.
- **color.blocks**: a character vector of colors to be used for the blocks.
- **color.cor**: a character vector of two colors. First one is for the negative correlation, second one is for the positive correlation.
- **var.names**: Optional parameter. A list of length the number of blocks in object$X, containing the names of the variables of each block. If NULL, the colnames of the data matrix are used.
- **showIntraLinks**: if TRUE, shows the correlation higher than the threshold inside each block.
- **line**: if TRUE, shows the overall expression of the selected variables. see examples.
- **size.legend**: size of the legend.
- **ncol.legend**: number of columns for the legend.
- **size.variables**: size of the variable labels.
- **size.labels**: size of the block labels.
- **legend**: Logical. Whether the legend should be added. Default is TRUE.
- **legend.title**: String. Name of the legend. Defaults to "Expression".
- **linkWidth**: Numeric. Specifies the range of sizes used for lines linking the correlated variables (see details). Must be of length 2 or 1. Default to c(1). See details.
- ... For object of class block.splsda, advanced plot parameters:
  - **var.adj**: Numeric. Adjusts the radial location of variable names in units of the arc band width. Positive values push feature names radially outward. Default to -0.33. See examples.
  - **block.labels.adj**: Numeric between -1 and 1. Adjusts the radial location of block names radially inward or outward. Default to 0. See examples.
  - **blocks.link**: Character vector of blocks. If provided, only correlations from features of these blocks are shown using links. See examples.

For object of class block.spls, all listed and advanced arguments passed to the block.splsda method.

- **group**: The grouping factor used when line = TRUE.
- **Y.name**: Character, the name of the Y block.
Details

circosPlot() function depicts correlations of variables selected with block.splsda or block.spls among different blocks, using a generalisation of the method presented in González et al 2012. If ncomp is specified, then only the variables selected on that component are displayed.

The linkWidth argument specifies the width of the links drawn. If a vector of length 2 is provided, the smaller value will correspond to a similarity values designated by cutoff argument, while the larger value will be used for a link with perfect similarity (1), if any.

Value

If saved in an object, the circos plot will output the similarity matrix and the names of the variables displayed on the plot (see attributes(object)).

  Y.name = 'protein', blocks.link = 'mrna')

---

### Description

The functions create a vector of n "contiguous" colors (except the color.mixo which are colors used internally to fit our logo colors).

### Usage

- `color.mixo(num.vector)`
- `color.GreenRed(n, alpha = 1)`
- `color.jet(n, alpha = 1)`
- `color.spectral(n, alpha = 1)`

### Arguments

- `num.vector` for `color.mixo` an integer vector specifying which colors to use in the mixOmics palette (there are only 10 colors available).
- `n` an integer, the number of colors (≥ 1) to be in the palette.
- `alpha` a numeric value between 0 and 1 for alpha channel (opacity).

### Details

The function `color.jet(n)` create color scheme, beginning with dark blue, ranging through shades of blue, cyan, green, yellow and red, and ending with dark red. This colors palette is suitable for displaying ordered (symmetric) data, with n giving the number of colors desired.

### Value

For `color.jet(n)`, `color.spectral(n)`, `color.GreenRed(n)` a character vector, cv, of color names. This can be used either to create a user-defined color palette for subsequent graphics by `palette(cv)`, a `col=` specification in graphics functions or in `par`.

For `color.mixo`, a vector of colors matching the mixOmics logo (10 colors max.)

}

# # --------------------------------
# mixOmics colors
# # --------------------------------
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
The 16S data from the Human Microbiome Project includes only the most diverse bodysites: Antecubital fossa (skin), Stool and Subgingival plaque (oral) and can be analysed using a multilevel approach to account for repeated measurements using our module mixMC. The data include 162 samples (54 unique healthy individuals) measured on 1,674 OTUs.

### Usage

```r
data(diverse.16S)
```

### Format

A list containing two data sets, `data.TSS` and `data.raw` and some meta data information:

- **list("data.TSS")** data frame with 162 rows (samples) and 1674 columns (OTUs). The prefiltered normalised data using Total Sum Scaling normalisation.
- **list("data.raw")** data frame with 162 rows (samples) and 1674 columns (OTUs). The prefiltered raw count OTU data which include a 1 offset (i.e. no 0 values).
- **list("taxonomy")** data frame with 1674 rows (OTUs) and 6 columns indicating the taxonomy of each OTU.
- **list("indiv")** data frame with 162 rows indicating sample meta data.
- **list("bodysite")** factor of length 162 indicating the bodysite with levels "Antecubital_fossa", "Stool" and "Subgingival_plaque".
- **list("sample")** vector of length 162 indicating the unique individual ID, useful for a multilevel approach to taken into account the repeated measured on each individual.

### Details

The data were downloaded from the Human Microbiome Project (HMP, http://hmpdacc.org/HMQCP/all/ for the V1-3 variable region). The original data contained 43,146 OTU counts for 2,911 samples measured from 18 different body sites. We focused on the first visit of each healthy individual and focused on the three most diverse habitats. The prefiltered dataset included 1,674 OTU counts. We strongly recommend to use log ratio transformations on the `data.TSS` normalised data, as implemented in the PLS and PCA methods, see details on www.mixOmics.org/mixMC.

The `data.raw` include a 1 offset in order to be log ratios transformed after TSS normalisation. Consequently, the `data.TSS` are TSS normalisation of `data.raw`. The CSS normalisation was performed on the original data (including zero values).
estim.regul

This function has been renamed 'image.tune.rcc', see image.tune.rcc.
This function has been renamed tune.pca.

Value

none
none
none

explained_variance  Calculates the proportion of explained variance of multivariate components

Description

explained_variance calculates the proportion of variance explained by a set of *orthogonal* variates / components and divides by the total variance in data using the definition of 'redundancy'. This applies to any component-based approaches where components are orthogonal. It is worth noting that any missing values are set to zero (which is the column mean for the centered input data) prior to calculation of total variance in the data. Therefore, this function would underestimate the total variance in presence of abundant missing values. One can use impute.nipals function to impute the missing values to avoid such behaviour.

Usage

explained_variance(data, variates, ncomp)
explained_variance

Arguments

- **data**: numeric matrix of predictors
- **variates**: variates as obtained from a pls object for instance
- **ncomp**: number of components. Should be lower than the number of columns of variates

Details

Variance explained by component $t_h$ in $X$ for dimension $h$:

$$Rd(X, t_h) = \frac{1}{p} \sum_{j=1}^{p} \text{cor}^2(X^j, t_h)$$

where $X^j$ is the variable centered and scaled, $p$ is the total number of variables.

Value

explained_variance returns a named numeric vector containing the proportion of explained variance for each variate after setting all missing values in the data to zero (see details).

```r
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic

toxicity.spls <- spls(X, Y, ncomp = 2, keepX = c(50, 50), keepY = c(10, 10))
ex = explained_variance(toxicity.spls$X, toxicity.spls$variates$X, ncomp = 2)

# ex should be the same as
toxicity.spls$prop_expl_var$X
```
get.confusion_matrix

Create confusion table and calculate the Balanced Error Rate

Description

Create confusion table between a vector of true classes and a vector of predicted classes, calculate the Balanced Error rate

Usage

get.confusion_matrix(truth, all.levels, predicted)

get.BER(confusion)

Arguments

truth A factor vector indicating the true classes of the samples (typically Y from the training set).
all.levels Levels of the 'truth' factor. Optional parameter if there are some missing levels in truth compared to the fitted predicted model
predicted Vector of predicted classes (typically the prediction from the test set). Can contain NA.
confusion result from a get.confusion_matrix to calculate the Balanced Error Rate

Details

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

Value

get.confusion_matrix returns a confusion matrix. get.BER returns the BER from a confusion matrix

X <- liver.toxicity$gene
Y <- as.factor(liver.toxicity$treatment[, 4])

## if training is performed on 4/5th of the original data
samp <- sample(1:5, nrow(X), replace = TRUE)
train <- samp == 1
# testing on the first fold
test <- setdiff(1:nrow(X), train)

plsda.train <- plsda(X[train, ], Y[train], ncomp = 2)
test.predict <- predict(plsda.train, X[test, ], dist = "max.dist")
Prediction <- test.predict$class$max.dist[, 2]

# the confusion table compares the real subtypes with the predicted subtypes for a 2 component model
confusion.mat = get.confusion_matrix(truth = Y[test],
predicted = Prediction)
get.BER(confusion.mat)

Description

This function provides a heatmap (checkerboard plot) of the cross-validation score obtained by the tune.rcc function.

Usage

## S3 method for class 'tune.rcc'
image(x, col = heat.colors, ...)

## S3 method for class 'tune.rcc'
plot(x, col = heat.colors, ...)

Arguments

x

object returned by tune.rcc.

col

a character string specifying the colors function to use: terrain.colors, topo.colors, rainbow or similar functions. Defaults to heat.colors.

... not used currently.
Details

plot.tune.rcc creates an image map of the matrix object$mat containing the cross-validation score obtained by the tune.rcc function. Also a color scales strip is plotted.

Value

none

plot(cv.score)

# image(cv.score) # same result as plot()

imgCor

Image Maps of Correlation Matrices between two Data Sets

Description

Display two-dimensional visualizations (image maps) of the correlation matrices within and between two data sets.

Usage

imgCor(
  X,  
  Y,  
  type = "combine",  
  X.var.names = TRUE,  
  Y.var.names = TRUE,  
  sideColors = TRUE,  
  interactive.dev = TRUE,  
  title = TRUE,  
  color,
Arguments

X numeric matrix or data frame \((n \times p)\), the observations on the \(X\) variables. NAs are allowed.

Y numeric matrix or data frame \((n \times q)\), the observations on the \(Y\) variables. NAs are allowed.

type character string, (partially) matching one of "combine" or "separated", determining the kind of plots to be produced. See Details.

X.var.names, Y.var.names logical, should the name of \(X\)- and/or \(Y\)-variables be shown? If TRUE (defaults) \(object\$names\$$X\) and/or \(object\$names\$$Y\) are used. Possible character vector with \(X\)- and/or \(Y\)-variable labels to use.

sideColors character vector of length two. The color name for horizontal and vertical side bars that may be used to annotate the \(X\) and \(Y\) correlation matrices.

interactive.dev logical. The current graphics device that will be opened is interactive?

title logical, should the main titles be shown?

color, xlab, ylab arguments passed to cim.

row.cex, col.cex positive numbers, used as \texttt{cex.axis} in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.

symkey Logical indicating whether the color key should be made symmetric about 0. Defaults to TRUE.

keysize positive numeric value indicating the size of the color key.

margins numeric vector of length two containing the margins (see \texttt{par(mar)}) for column and row names respectively.

lhei, lwid arguments passed to layout to divide the device up into two rows and two columns, with the row-heights \(lhei\) and the column-widths \(lwid\).

Details

If type="combine", the correlation matrix is computed of the combined matrices \texttt{cbind(X, Y)} and then plotted. If type="separate", three correlation matrices are computed, \texttt{cor(X)}, \texttt{cor(Y)} and \texttt{cor(X, Y)} and plotted separately on a device. In both cases, a color correlation scales strip is plotted.
The correlation matrices are pre-processed before calling the \texttt{image} function in order to get, as in the numerical representation, the diagonal from upper-left corner to bottom-right one. Missing values are handled by casewise deletion in the \texttt{imgCor} function. If \texttt{X.names = FALSE}, the name of each X-variable is hidden. Default value is \texttt{TRUE}. If \texttt{Y.names = FALSE}, the name of each Y-variable is hidden. Default value is \texttt{TRUE}.

Value

\texttt{NULL (invisibly)}

\texttt{cor, image, color.jet}.

Examples

\begin{verbatim}
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene

## 'combine' type plot (default)
imgCor(X, Y)

## Not run:
## 'separate' type plot
imgCor(X, Y, type = "separate")

## 'separate' type plot without the name of datas
imgCor(X, Y, X.var.names = FALSE, Y.var.names = FALSE, type = "separate")

## End(Not run)
\end{verbatim}

\textbf{impute.nipals} \hspace{1cm} \emph{Impute missing values using NIPALS algorithm}

Description

This function uses \texttt{nipals} function to decompose \( X \) into a set of components \( t \), (pseudo-) singular-values \( \text{eig} \), and feature loadings \( p \). The original matrix is then approximated/reconstituted using the following equation:

\[ \hat{X} = t \ast \text{diag(eig)} \ast t(p) \]

The missing values from \( X \) are then approximated from this matrix. It is best to ensure enough number of components are used in order to best impute the missing values.
Usage

impute.nipals(X, ncomp, ...)

Arguments

X A numeric matrix containing missing values
ncomp Positive integer, the number of components to derive from X using the nipals function and reconstitute the original matrix
... Optional arguments passed to nipals

Value

A numeric matrix with missing values imputed.

Author(s)

Al J Abadi

See Also

impute.nipals, pca

Examples

data("nutrimouse")
X <- data.matrix(nutrimouse$lipid)
## add missing values to X to impute and compare to actual values
set.seed(42)
na.ind <- sample(seq_along(X), size = 10)
true.values <- X[na.ind]
X[na.ind] <- NA
X.impute <- impute.nipals(X = X, ncomp = 5)
## compare
round(X.impute[na.ind], 2)
true.values

ipca

Independent Principal Component Analysis

Description

Performs independent principal component analysis on the given data matrix, a combination of Principal Component Analysis and Independent Component Analysis.
Usage

ipca(
  X,
  ncomp = 2,
  mode = "deflation",
  fun = "logcosh",
  scale = FALSE,
  w.init = NULL,
  max.iter = 200,
  tol = 1e-04
)

Arguments

X  a numeric matrix (or data frame).

ncomp integer, number of independent component to choose. Set by default to 3.

mode character string. What type of algorithm to use when estimating the unmixing matrix, choose one of "deflation", "parallel". Default set to deflation.

fun the function used in approximation to neg-entropy in the FastICA algorithm. Default set to logcosh, see details of FastICA.

scale (Default=FALSE) Logical indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.

w.init initial un-mixing matrix (unlike fastICA, this matrix is fixed here).

max.iter integer, the maximum number of iterations.

tol a positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged, see fastICA package.

Details

In PCA, the loading vectors indicate the importance of the variables in the principal components. In large biological data sets, the loading vectors should only assign large weights to important variables (genes, metabolites ...). That means the distribution of any loading vector should be super-Gaussian: most of the weights are very close to zero while only a few have large (absolute) values.

However, due to the existence of noise, the distribution of any loading vector is distorted and tends toward a Gaussian distribution according to the Central Limit Theorem. By maximizing the non-Gaussianity of the loading vectors using FastICA, we obtain more noiseless loading vectors. We then project the original data matrix on these noiseless loading vectors, to obtain independent principal components, which should be also more noiseless and be able to better cluster the samples according to the biological treatment (note, IPCA is an unsupervised approach).

Algorithm
1. The original data matrix is centered.
2. PCA is used to reduce dimension and generate the loading vectors.
3. ICA (FastICA) is implemented on the loading vectors to generate independent loading vectors.
4. The centered data matrix is projected on the independent loading vectors to obtain the independent principal components.

Value

ipca returns a list with class "ipca" containing the following components:

- `ncomp`: the number of independent principal components used.
- `unmixing`: the unmixing matrix of size (ncomp x ncomp)
- `mixing`: the mixing matrix of size (ncomp x ncomp)
- `X`: the centered data matrix
- `x`: the independent principal components
- `loadings`: the independent loading vectors
- `kurtosis`: the kurtosis measure of the independent loading vectors
- `prop_expl_var`: Proportion of the explained variance of derived components, after setting possible missing values to zero.

### Description

The 16S data come from Koren et al. (2011) and compared the bodysites oral, gut and plaque microbial communities in patients with atherosclerosis. The data can be analysed with our mixMC module. The data include 43 samples measured on 980 OTUs.

### Usage

data(Koren.16S)

### Format

A list containing two data sets, `data.TSS` and `data.raw` and some meta data information:

- `list("data.TSS")` data frame with 43 rows (samples) and 980 columns (OTUs). The prefiltered normalised data using Total Sum Scaling normalisation.
- `list("data.raw")` data frame with 43 rows (samples) and 980 columns (OTUs). The prefiltered raw count OTU data which include a 1 offset (i.e. no 0 values).
- `list("taxonomy")` data frame with 980 rows (OTUs) and 7 columns indicating the taxonomy of each OTU.
- `list("indiv")` data frame with 43 rows indicating sample meta data.
- `list("bodysite")` factor of length 43 indicating the bodysite with levels arterial plaque, saliva and stool.
Details

The data are from Koren et al. (2011) who examined the link between oral, gut and plaque microbial communities in patients with atherosclerosis and controls. Only healthy individuals were retained in the analysis. This study contained partially repeated measures from multiple sites including 15 unique patients samples from saliva and stool, and 13 unique patients only sampled from arterial plaque samples and we therefore considered a non multilevel analysis for that experimental design. After prefiltering, the data included 973 OTU for 43 samples. We strongly recommend to use log ratio transformations on the data.TSS normalised data, as implemented in the PLS and PCA methods, see details on www.mixOmics.org/mixMC.

The data.raw include a 1 offset in order to be log ratios transformed after TSS normalisation. Consequently, the data.TSS are TSS normalisation of data.raw. The CSS normalisation was performed on the original data (including zero values)

Value

none

Source

The raw data were downloaded from the QIITA database. Filtering and normalisation described in our website www.mixOmics.org/mixMC

liver.toxicity Liver Toxicity Data

Description
This data set contains the expression measure of 3116 genes and 10 clinical measurements for 64 subjects (rats) that were exposed to non-toxic, moderately toxic or severely toxic doses of acetaminophen in a controlled experiment.

Usage
data(liver.toxicity)

Format
A list containing the following components:

- **list("gene")** data frame with 64 rows and 3116 columns. The expression measure of 3116 genes for the 64 subjects (rats).
- **list("clinic")** data frame with 64 rows and 10 columns, containing 10 clinical variables for the same 64 subjects.
- **list("treatment")** data frame with 64 rows and 4 columns, containing the treatment information on the 64 subjects, such as doses of acetaminophen and times of necropsies.
- **list("gene.ID")** data frame with 3116 rows and 2 columns, containing geneBank IDs and gene titles of the annotated genes

Details
The data come from a liver toxicity study (Bushel et al., 2007) in which 64 male rats of the inbred strain Fisher 344 were exposed to non-toxic (50 or 150 mg/kg), moderately toxic (1500 mg/kg) or severely toxic (2000 mg/kg) doses of acetaminophen (paracetamol) in a controlled experiment. Necropsies were performed at 6, 18, 24 and 48 hours after exposure and the mRNA from the liver was extracted. Ten clinical chemistry measurements of variables containing markers for liver injury are available for each subject and the serum enzymes levels are measured numerically. The data were further normalized and pre-processed by Bushel et al. (2007).
Value

none

logratio-transformations

Log-ratio transformation

Description

This function applies a log transformation to the data, either CLR or ILR

Usage

logratio.transfo(X, logratio = c("none", "CLR", "ILR"), offset = 0)

Arguments

X numeric matrix of predictors
logratio log-ratio transform to apply, one of "none", "CLR" or "ILR"
offset Value that is added to X for CLR and ILR log transformation. Default to 0.

Details

logratio.transfo applies a log transformation to the data, either CLR (centered log ratio transformation) or ILR (Isometric Log Ratio transformation). In the case of CLR log-transformation, X needs to be a matrix of non-negative values and offset is used to shift the values away from 0, as commonly done with counts data.

Value

logratio.transfo simply returns the log-ratio transformed data.

Description

Classification given Probabilities

Converts a matrix in which each row sums to 1 into the nearest matrix of \((0,1)\) indicator variables.

Usage

map(Y)

Arguments

Y
A matrix (for example a matrix of conditional probabilities in which each row sums to 1).

Value

A integer vector with one entry for each row of Y, in which the \(i\)-th value is the column index at which the \(i\)-th row of Y attains a maximum.

**mat.rank**

*Matrix Rank*

**Description**

This function estimates the rank of a matrix.

**Usage**

`mat.rank(mat, tol)`

**Arguments**

- `mat`: a numeric matrix or data frame that can contain missing values.
- `tol`: positive real, the tolerance for singular values, only those with values larger than `tol` are considered non-zero.

**Details**

`mat.rank` estimate the rank of a matrix by computing its singular values $d[i]$ (using `nipals`). The rank of the matrix can be defined as the number of singular values $d[i] > 0$.

If `tol` is missing, it is given by `tol = max(dim(mat))*(max(d) *.Machine$double.eps`.

**Value**

The returned value is a list with components:

- `rank`: a integer value, the matrix rank.
- `tol`: the tolerance used for singular values.

Examples

```r
## Hilbert matrix
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
mat <- hilbert(16)
mat.rank(mat)

## Not run:
## Hilbert matrix with missing data
idx.na <- matrix(sample(c(0, 1, 1, 1, 1), 36, replace = TRUE), ncol = 6)
m.na <- m <- hilbert(9)[, 1:6]
m.na[idx.na == 0] <- NA
mat.rank(m)
mat.rank(m.na)
## End(Not run)
```

Description

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group and generalised PLS (unsupervised analysis).

Usage

```r
mint.block.pls(
  X,
  Y,
  indY,
  study,
  ncomp = 2,
  design,
  scheme,
  mode,
  scale = TRUE,
  init,
  tol = 1e-06,
  max.iter = 100,
)```
Arguments

X
A named list of data sets (called ‘blocks’) measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.

Y
Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see ?mint.block.splsda for supervised classification and factor response).

indY
To be supplied if Y is missing, indicates the position of the matrix / vector response in the list X

study
Factor, indicating the membership of each sample to each of the studies being combined

ncomp
the number of components to include in the model. Default to 2. Applies to all blocks.

design
numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c(‘null’, ‘full’) indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.

scheme
Character, one of ‘horst’, ‘factorial’ or ‘centroid’. Default = ‘horst’, see reference.

mode
Character string indicating the type of PLS algorithm to use. One of “regression”, “canonical”, “invariant” or “classic”. See Details.

scale
Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

init
Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y (‘svd’) or each block independently (‘svd.single’). Default = svd.single

tol
Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter
Integer, the maximum number of iterations. Default to 100.

near.zero.var
Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs
Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.
Details

The function fits multi-group generalised PLS models with a specified number of ncomp components. An outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in ?pls).

Value

mint.block.pls returns an object of class "mint.pls", "block.pls", a list that contains the following components:

- X: the centered and standardized original predictor matrix.
- Y: the centered and standardized original response vector or matrix.
- ncomp: the number of components included in the model for each block.
- mode: the algorithm used to fit the model.
- mat.c: matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
- variates: list containing the X and Y variates.
- loadings: list containing the estimated loadings for the variates.
- names: list containing the names to be used for individuals and variables.
- nzv: list containing the zero- or near-zero predictors information.
- tol: the tolerance used in the iterative algorithm, used for subsequent S3 methods
- max.iter: the maximum number of iterations, used for subsequent S3 methods
- iter: Number of iterations of the algorithm for each component

**mint.block.spls**

NP-integration for integration with variable selection

**Description**

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies (P-integration) using variants of sparse multi-group and generalised PLS with variable selection (unsupervised analysis).
Usage

```r
mint.block.spls(
    X,
    Y,
    indY,
    study,
    ncomp = 2,
    keepX,
    keepY,
    design,
    scheme,
    mode,
    scale = TRUE,
    init,
    tol = 1e-06,
    max.iter = 100,
    near.zero.var = FALSE,
    all.outputs = TRUE
)
```

Arguments

- **X**: A named list of data sets (called ‘blocks’) measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.

- **Y**: Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see `?mint.block.splsda` for supervised classification and factor response).

- **indY**: To be supplied if Y is missing, indicates the position of the matrix / vector response in the list X.

- **study**: Factor, indicating the membership of each sample to each of the studies being combined.

- **ncomp**: The number of components to include in the model. Default to 2. Applies to all blocks.

- **keepX**: A named list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.

- **keepY**: Only if Y is provided (and not indY). Each entry is the number of variables to select in each of the blocks of Y for each component.

- **design**: Numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c(‘null’, ‘full’) indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in `block.splsda`). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
mint.block.spls

Character, one of 'horst', 'factorial' or 'centroid'. Default = 'horst', see reference.

mode

Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

scale

Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE).

init

Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ('svd') or each block independently ('svd.single'). Default = svd.single.

tol

Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter

Integer, the maximum number of iterations. Default to 100.

near.zero.var

Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs

Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

The function fits sparse multi-group generalised PLS models with a specified number of ncomp components. An outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

mint.pca

P-integration with Principal Component Analysis

Description
Function to integrate and combine multiple independent studies measured on the same variables or
predictors (P-integration) using a multigroup Principal Component Analysis.

Usage
mint.pca(
  X,
  ncomp = 2,
  study,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  verbose.call = FALSE
)

Arguments

X numeric matrix of predictors combining multiple independent studies on the
same set of predictors. NAs are allowed.
ncomp Number of components to include in the model (see Details). Default to 2
study factor indicating the membership of each sample to each of the studies being
combined
scale Logical. If scale = TRUE, each block is standardized to zero means and unit
variances. Default = TRUE.
tol Convergence stopping value.
max.iter integer, the maximum number of iterations.
verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the
returned object will contain the variable values for all parameters. Note that this
may cause large memory usage.
mint.pca

Details

mint.pca fits a vertical PCA model with ncomp components in which several independent studies measured on the same variables are integrated. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Missing values are handled by being disregarded during the cross product computations in the algorithm without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

Useful graphical outputs are available, e.g. plotIndiv, plotLoadings, plotVar.

Value

mint.pca returns an object of class "mint.pca", "pca", a list that contains the following components:

- X the centered and standardized original predictor matrix.
- ncomp the number of components included in the model.
- study The study grouping factor
- sdev the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix or by using NIPALS.
- center, scale the centering and scaling used, or FALSE.
- rotation the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors).
- loadings same as 'rotation' to keep the mixOmics spirit
- x the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation/loadings matrix), also called the principal components.
- variates same as 'x' to keep the mixOmics spirit
- prop_expl_var Proportion of the explained variance from the multivariate model after setting possible missing values to zero in the data.
- names list containing the names to be used for individuals and variables.
- call if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessable via this component.

mint.pls

P-integration

Description

Function to integrate and combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group PLS (unsupervised analysis).

Usage

mint.pls(
  X,
  Y,
  ncomp = 2,
  mode = c("regression", "canonical", "invariant", "classic"),
  study,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)

Arguments

X
numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.

Y
Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see mint.plsda for supervised classification and factor response)

ncomp
Positive Integer. The number of components to include in the model. Default to 2.
mint.pls

mode
Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

study
Factor, indicating the membership of each sample to each of the studies being combined

scale
Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

tol
Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter
Integer, the maximum number of iterations. Default to 100.

near.zero.var
Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs
Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call
Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

mint.pls fits a vertical PLS-DA models with ncomp components in which several independent studies measured on the same variables are integrated. The aim is to explain the continuous outcome Y. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Multi (continuous) response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm mint.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in ?pls).

Useful graphical outputs are available, e.g. plotIndiv, plotLoadings, plotVar.

Value

mint.pls returns an object of class "mint.pls", "pls", a list that contains the following components:

X the centered and standardized original predictor matrix.

Y the centered and standardized original response vector or matrix.

ncomp the number of components included in the model.

study The study grouping factor

mode the algorithm used to fit the model.

variates list containing the variates of X - global variates.
loadings list containing the estimated loadings for the variates - global loadings.

variates.partial list containing the variates of X relative to each study - partial variates.

loadings.partial list containing the estimated loadings for the partial variates - partial loadings.

names list containing the names to be used for individuals and variables.

nzv list containing the zero- or near-zero predictors information.

iter Number of iterations of the algorithm for each component

prop_expl_var Percentage of explained variance for each component and each study (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).

call if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessible via this component

mint.plsda

P-integration with Projection to Latent Structures models (PLS) with Discriminant Analysis

Description

Function to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group PLS-DA for supervised classification.

Usage

mint.plsda(
  X,
  Y,
  ncomp = 2,
  study,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)

Arguments

X numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.

Y A factor or a class vector indicating the discrete outcome of each sample.

ncomp Positive Integer. The number of components to include in the model. Default to 2.

study Factor, indicating the membership of each sample to each of the studies being combined

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter Integer, the maximum number of iterations. Default to 100.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.
mint.plsda

all.outputs Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

mint.plsda function fits a vertical PLS-DA models with ncomp components in which several independent studies measured on the same variables are integrated. The aim is to classify the discrete outcome Y. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study, and where all outcome categories are represented.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm mint.plsda without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the impute.nipals function.

The type of deflation used is 'regression' for discriminant algorithms. i.e. no deflation is performed on Y.

Useful graphical outputs are available, e.g. plotIndiv, plotLoadings, plotVar.

Value

mint.plsda returns an object of class "mint.plsda","plsda", a list that contains the following components:

X the centered and standardized original predictor matrix.
Y original factor
ind.mat the centered and standardized original response vector or matrix.
ncomp the number of components included in the model.
study The study grouping factor
mode the algorithm used to fit the model.
variates list containing the variates of X - global variates.
loadings list containing the estimated loadings for the variates - global loadings.
variates.partial list containing the variates of X relative to each study - partial variates.
loadings.partial list containing the estimated loadings for the partial variates - partial loadings.
names list containing the names to be used for individuals and variables.
nzv list containing the zero- or near-zero predictors information.
iter Number of iterations of the algorithm for each component
prop_expl_var Percentage of explained variance for each component and each study after setting possible missing values to zero (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).

call if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessable via this component

mint.spls

P-integration with variable selection

Description

Function to integrate and combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group sparse PLS for variable selection (unsupervised analysis).
Usage

mint.spls(
  X,
  Y,
  ncomp = 2,
  mode = c("regression", "canonical", "invariant", "classic"),
  study,
  keepX = rep(ncol(X), ncomp),
  keepY = rep(ncol(Y), ncomp),
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE,
  verbose.call = FALSE
)

Arguments

X numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.

Y Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see mint.splsda for supervised classification and factor response)

ncomp Positive Integer. The number of components to include in the model. Default to 2.

mode Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

study Factor, indicating the membership of each sample to each of the studies being combined

keepX numeric vector indicating the number of variables to select in X on each component. By default all variables are kept in the model.

keepY numeric vector indicating the number of variables to select in Y on each component. By default all variables are kept in the model.

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter Integer, the maximum number of iterations. Default to 100.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

all.outputs Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.
verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

mint.spls fits a vertical sparse PLS-DA models with ncomp components in which several independent studies measured on the same variables are integrated. The aim is to explain the continuous outcome Y and selecting correlated features between both data sets X and Y. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm mint.spls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in ?pls).

Variable selection is performed on each component for each block of X, and for Y if specified, via input parameter keepX and keepY.

Useful graphical outputs are available, e.g. plotIndiv, plotLoadings, plotVar.

Value

mint.spls returns an object of class "mint.spls", "spls", a list that contains the following components:

X numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
Y the centered and standardized original response vector or matrix.
ncomp the number of components included in the model.
study The study grouping factor
mode the algorithm used to fit the model.
keepX Number of variables used to build each component of X
keepY Number of variables used to build each component of Y
variates list containing the variates of X - global variates.
loadings list containing the estimated loadings for the variates - global loadings.
variates.partial list containing the variates of X relative to each study - partial variates.
loadings.partial list containing the estimated loadings for the partial variates - partial loadings.
names list containing the names to be used for individuals and variables.
nzv list containing the zero- or near-zero predictors information.
Number of iterations of the algorithm for each component

The amount of the variance explained by each variate / component divided by the total variance in the data for each study (after removing the possible missing values) using the definition of ‘redundancy’. Note that contrary to PCA, this amount may not decrease in the following components as the aim of the method is not to maximise the variance, but the covariance between data sets (including the dummy matrix representation of the outcome variable in case of the supervised approaches).

If `verbose.call = FALSE`, then just the function call is returned. If `verbose.call = TRUE` then all the inputted values are accessible via this component.

mixOmics

PLS-derived methods: one function to rule them all!

Description

This is the documentation for mixOmics function from mixOmics package. For package documentation refer to help(package='mixOmics')

Usage

mixOmics(
X,  
Y,  
indY,  
study,  
ncomp,  
keepX,  
keepY,  
design,  
tau = NULL,  
scheme,  
mode = c("regression", "canonical", "invariant", "classic"),  
scale,  
init,  
tol = 1e-06,  
max.iter = 100,  
near.zero.var = FALSE  
)

Arguments

X

Input data. Either a matrix or a list of data sets (called 'blocks') matching on the same samples. Data should be arranged in samples x variables, with samples order matching in all data sets.

Y

Outcome. Either a numeric matrix of responses or a factor or a class vector for the discrete outcome.

indY

To supply if Y is missing, indicates the position of the outcome in the list X

study

grouping factor indicating which samples are from the same study

ncomp

If X is a data matrix, ncomp is a single value. If X is a list of data sets, ncomp is a numeric vector of length the number of blocks in X. The number of components to include in the model for each block (does not necessarily need to take the same value for each block).

keepX

Number of variables to keep in the X-loadings

keepY

Number of variables to keep in the Y-loadings
design numeric matrix of size (number of blocks) x (number of blocks) with only 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If \( Y \) is provided instead of \( \text{indY} \), the design matrix is changed to include relationships to \( Y \).

tau numeric vector of length the number of blocks in \( X \). Each regularization parameter will be applied on each block and takes the value between 0 (no regularisation) and 1. If tau = "optimal" the shrinkage parameters are estimated for each block and each dimension using the Schafer and Strimmer (2005) analytical formula.

scheme Either "horst", "factorial" or "centroid" (Default: "centroid"), see reference paper.

mode character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

init Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of \( X \) with \( Y \) ("svd") or each block independently ("svd.single"). Default to "svd".

tol Convergence stopping value.

max.iter integer, the maximum number of iterations.

near.zero.var Logical, see the internal \nearZeroVar\ function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE

Details

This function performs one of the PLS derived methods included in the mixOmics package that is the most appropriate for your input data, one of (mint).(block).(s)pls(da) depending on your input data (single data, list of data, discrete outcome, . . .)

This function performs one of the PLS derived methods included in the mixOmics package that is the most appropriate for your input data, one of (mint).(block).(s)pls(da).

If your input data \( X \) is a matrix, then the algorithm is directed towards one of (mint).(s)pls(da) depending on your input data \( Y \) (factor for the discrete outcome directs the algorithm to DA analysis) and whether you input a study parameter (MINT analysis) or a keepX parameter (sparse analysis).

If your input data \( X \) is a list of matrices, then the algorithm is directed towards one of (mint).block.(s)pls(da) depending on your input data \( Y \) (factor for the discrete outcome directs the algorithm to DA analysis) and whether you input a study parameter (MINT analysis) or a keepX parameter (sparse analysis).

More details about the PLS modes in \?pls.

multidrug

Multidrug Resistance Data

Description
This data set contains the expression of 48 known human ABC transporters with patterns of drug activity in 60 diverse cancer cell lines (the NCI-60) used by the National Cancer Institute to screen for anticancer activity.

Usage
data(multidrug)

Format
A list containing the following components:

list("ABC.trans") data matrix with 60 rows and 48 columns. The expression of the 48 human ABC transporters.

list("compound") data matrix with 60 rows and 1429 columns. The activity of 1429 drugs for the 60 cell lines.

list("comp.name") character vector. The names or the NSC No. of the 1429 compounds.

list("cell.line") a list containing two character vector components: Sample the names of the 60 cell line which were analysed, and Class the phenotypes of the 60 cell lines.

## -- directed towards mint.pls framework because of the study factor

out = mixOmics(X = stemcells$gene, Y = stemcells$celltype, ncomp = 2,
study = stemcells$study, keepX = c(10, 5, 15))

## End(Not run)
Details

The data come from a pharmacogenomic study (Szakacs et al., 2004) in which two kinds of measurements acquired on the NCI-60 cancer cell lines are considered:

- the expression of the 48 human ABC transporters measured by real-time quantitative RT-PCR for each cell line;
- the activity of 1429 drugs expressed as $G_{50}$ which corresponds to the concentration at which the drug induces 50% inhibition of cellular growth for the cell line tested.

The NCI-60 panel includes cell lines derived from cancers of colorectal (7 cell lines), renal (8), ovarian (6), breast (8), prostate (2), lung (9) and central nervous system origin (6), as well as leukemias (6) and melanomas (8). It was set up by the Developmental Therapeutics Program of the National Cancer Institute (NCI, one of the U.S. National Institutes of Health) to screen the toxicity of chemical compound repositories. The expressions of the 48 human ABC transporters is available as a supplement to the paper of Szakacs et al. (2004).

The drug dataset consists of 118 compounds whose mechanisms of action are putatively classifiable (Weinstein et al., 1992) and a larger set of 1400 compounds that have been tested multiple times and whose screening data met quality control criteria described elsewhere (Scherf et al., 2000). The two were combined to form a joint dataset that included 1429 compounds.

Value

none

Source

The NCI dataset was downloaded from The Genomics and Bioinformatics Group Supplemental Table S1 to the paper of Szakacs et al. (2004), http://discover.nci.nih.gov/abc/2004_cancercell_abstract.jsp#supplement

The two drug data sets are a companion resource for the paper of Scherf et al. (2000), and was downloaded from http://discover.nci.nih.gov/datasetsNature2000.jsp.

References

nearZeroVar  	Identification of zero- or near-zero variance predictors  

Description

Borrowed from the caret package. It is used as an internal function in the PLS methods, but can also be used as an external function, in particular when the data contain a lot of zeroes values and need to be pre-filtered beforehand.

Usage

nearZeroVar(x, freqCut = 95/5, uniqueCut = 10)

Arguments

- x  
a numeric vector or matrix, or a data frame with all numeric data.
- freqCut  
the cutoff for the ratio of the most common value to the second most common value.
- uniqueCut  
the cutoff for the percentage of distinct values out of the number of total samples.

Details

This function diagnoses predictors that have one unique value (i.e. are zero variance predictors) or predictors that are have both of the following characteristics: they have very few unique values relative to the number of samples and the ratio of the frequency of the most common value to the frequency of the second most common value is large.

For example, an example of near zero variance predictor is one that, for 1000 samples, has two distinct values and 999 of them are a single value.

To be flagged, first the frequency of the most prevalent value over the second most frequent value (called the “frequency ratio”) must be above freqCut. Secondly, the “percent of unique values,” the number of unique values divided by the total number of samples (times 100), must also be below uniqueCut.

In the above example, the frequency ratio is 999 and the unique value percentage is 0.0001.

Value

nearZeroVar returns a list that contains the following components:

- Position  
a vector of integers corresponding to the column positions of the problematic predictors that will need to be removed.
- Metrics  
a data frame containing the zero- or near-zero predictors information with columns: freqRatio, the ratio of frequencies for the most common value over the second most common value and, percentUnique, the percentage of unique data points out of the total number of data points.

nzv = nearZeroVar(diverse.16S$data.raw)
length(nzv$Position) # those would be removed for the default frequency cut

network
Relevance Network for (r)CCA and (s)PLS regression

Description
Display relevance associations network for (regularized) canonical correlation analysis and (sparse) PLS regression. The function avoids the intensive computation of Pearson correlation matrices on large data set by calculating instead a pair-wise similarity matrix directly obtained from the latent components of our integrative approaches (CCA, PLS, block.pls methods). The similarity value between a pair of variables is obtained by calculating the sum of the correlations between the original variables and each of the latent components of the model. The values in the similarity matrix can be seen as a robust approximation of the Pearson correlation (see González et al. 2012 for a mathematical demonstration and exact formula). The advantage of relevance networks is their ability to simultaneously represent positive and negative correlations, which are missed by methods based on Euclidean distances or mutual information. Those networks are bipartite and thus only a link between two variables of different types can be represented. The network can be saved in a .glm format using the igraph package, the function write.graph and extracting the output object$gR, see details.

Usage

network(
  mat,
  comp = NULL,
  blocks = c(1, 2),
  cutoff = 0,
  row.names = TRUE,
  col.names = TRUE,
  block.var.names = TRUE,
  graph.scale = 0.5,
  size.node = 0.5,
  color.node = NULL,
  shape.node = NULL,
  alpha.node = 0.85,
cex.node.name = NULL,
color.edge = color.GreenRed(100),
lty.edge = "solid",
lwd.edge = 1,
show.edge.labels = FALSE,
cex.edge.label = 1,
show.color.key = TRUE,
symkey = TRUE,
keysize = c(1, 1),
keysize.label = 1,
breaks,
interactive = FALSE,
layout.fun = NULL,
save = NULL,
name.save = NULL,
plot.graph = TRUE
)

Arguments

mat numeric matrix of values to be represented. Alternatively, an object from one of the following models: mix pls, plsda, mixo_spls, splsda, rcc, sgcca, rgcca, sgccda.
comp atomic or vector of positive integers. The components to adequately account for the data association.Defaults to comp = 1.
blocks a vector indicating the block variables to display.
cutoff numeric value between 0 and 1. The tuning threshold for the relevant associations network (see Details).
row.names, col.names character vector containing the names of X- and Y-variables.
block.var.names either a list of vector components for variable names in each block or FALSE for no names. If TRUE, the columns names of the blocks are used as names.
graph.scale numeric between 0 and 1 which alters the scale of the entire plot. Increasing the value decreases the size of nodes and increases their distance from one another. Defaults to 0.5.
size.node numeric between 0 and 1 which determines the relative size of nodes. Defaults to 0.5.
color.node vector of length two, the colors of the X and Y nodes (see Details).
shape.node character vector of length two, the shape of the X and Y nodes (see Details).
alpha.node numeric between 0 and 1 which determines the opacity of nodes. Only used in block objects.
cex.node.name the font size for the node labels.
color.edge vector of colors or character string specifying the colors function to using to color the edges, set to default to color.GreenRed(100) but other palettes can be chosen (see Details and Examples).
network

**lty.edge**
character vector of length two, the line type for the edges (see Details).

**lwd.edge**
vector of length two, the line width of the edges (see Details).

**show.edge.labels**
logical. If TRUE, plot association values as edge labels (defaults to FALSE).

**cex.edge.label**
the font size for the edge labels.

**show.color.key**
Logical. If TRUE a color key should be plotted.

**symkey**
Logical indicating whether the color key should be made symmetric about 0. Defaults to TRUE.

**keysize**
umeric value indicating the size of the color key.

**keysize.label**
vector of length 1, indicating the size of the labels and title of the color key.

**breaks**
(optional) either a numeric vector indicating the splitting points for binning mat into colors, or a integer number of break points to be used, in which case the break points will be spaced equally between min(mat) and max(mat).

**interactive**
logical. If TRUE, a scrollbar is created to change the cutoff value interactively (defaults to FALSE). See Details.

**layout.fun**
a function. It specifies how the vertices will be placed on the graph. See help(layout) in the igraph package. Defaults to layout.fruchterman.reingold.

**save**
should the plot be saved? If so, argument to be set either to 'jpeg', 'tiff', 'png' or 'pdf'.

**name.save**
character string giving the name of the saved file.

**plot.graph**
logical. If TRUE (default), plotting window will be filled with network. If FALSE, then no graph will be plotted, though the return value of the function is the exact same.

### Details

**network** allows to infer large-scale association networks between the X and Y datasets in rcc or spls. The output is a graph where each X- and Y-variable corresponds to a node and the edges included in the graph portray associations between them.

In rcc, to identify X-Y pairs showing relevant associations, **network** calculate a similarity measure between X and Y variables in a pair-wise manner: the scalar product value between every pairs of vectors in dimension length(comp) representing the variables X and Y on the axis defined by Z_i with i in comp, where Z_i is the equiangular vector between the i-th X and Y canonical variate.

In spls, if object$mode is regression, the similarity measure between X and Y variables is given by the scalar product value between every pairs of vectors in dimension length(comp) representing the variables X and Y on the axis defined by U_i with i in comp, where U_i is the i-th X variate. If object$mode is canonical then X and Y are represented on the axis defined by U_i and V_i respectively.

Variable pairs with a high similarity measure (in absolute value) are considered as relevant. By changing the cut-off, one can tune the relevance of the associations to include or exclude relationships in the network.

**interactive=TRUE** open two device, one for association network, one for scrollbar, and define an interactive process: by clicking either at each end (− or +) of the scrollbar or at middle portion of this. The position of the slider indicate which is the ‘cutoff’ value associated to the display network.
The network can be saved in a .glm format using the `igraph` package, the function `write.graph` and extracting the output `object$gR`.

The interactive process is terminated by clicking the second button and selecting Stop from the menu, or from the Stop menu on the graphics window.

The `color.node` is a vector of length two, of any of the three kind of R colors, i.e., either a color name (an element of `colors()`), a hexadecimal string of the form "#rrggbb", or an integer i meaning `palette()[i]`. `color.node[1]` and `color.node[2]` give the color for filled nodes of the X- and Y-variables respectively. Defaults to `c("white", "white")`.

`color.edge` give the color to edges with colors corresponding to the values in `mat`. Defaults to `color.GreenRed(100)` for negative (green) and positive (red) correlations. We also propose other palettes of colors, such as `color.jet` and `color.spectral`, see help on those functions, and examples below. Other palette of colors from the stats package can be used too.

`shape.node[1]` and `shape.node[2]` provide the shape of the nodes associate to X- and Y-variables respectively. Current acceptable values are "circle" and "rectangle". Defaults to `c("circle", "rectangle")`.

`lty.edge[1]` and `lty.edge[2]` give the line type to edges with positive and negative weight respectively. Can be one of "solid", "dashed", "dotted", "dotdash", "longdash" and "twodash". Defaults to `c("solid", "solid")`.

`lwd.edge[1]` and `lwd.edge[2]` provide the line width to edges with positive and negative weight respectively. This attribute is of type double with a default of c(1, 1).

Value

`network` return a list containing the following components:

- `M` the correlation matrix used by `network`.
- `gR` a graph object to save the graph for cytoscape use (requires to load the `igraph` package).

Warning

If the number of variables is high, the generation of the network generation can take some time.

**nipals**

*Non-linear Iterative Partial Least Squares (NIPALS) algorithm*

**Description**

This function performs NIPALS algorithm, i.e. the singular-value decomposition (SVD) of a data table that can contain missing values.

**Usage**

```r
nipals(X, ncomp = 2, max.iter = 500, tol = 1e-06)
```

**Arguments**

- **X**
  a numeric matrix (or data frame) which provides the data for the principal components analysis. It can contain missing values in which case `center = TRUE` is used as required by the `nipals` function.

- **ncomp**
  Integer, if data is complete `ncomp` decides the number of components and associated eigenvalues to display from the `pcasvd` algorithm and if the data has missing values, `ncomp` gives the number of components to keep to perform the reconstitution of the data using the NIPALS algorithm. If `NULL`, function sets `ncomp = min(nrow(X),ncol(X))`

- **max.iter**
  Integer, the maximum number of iterations in the NIPALS algorithm.

- **tol**
  Positive real, the tolerance used in the NIPALS algorithm.

**Details**

The NIPALS algorithm (Non-linear Iterative Partial Least Squares) has been developed by H. Wold at first for PCA and later-on for PLS. It is the most commonly used method for calculating the principal components of a data set. It gives more numerically accurate results when compared with the SVD of the covariance matrix, but is slower to calculate.

This algorithm allows to realize SVD with missing data, without having to delete the rows with missing data or to estimate the missing data.
The `nutrimouse` dataset contains the expression measure of 120 genes potentially involved in nutritional problems and the concentrations of 21 hepatic fatty acids for forty mice.

Usage

```r
data(nutrimouse)
```

Format

A list containing the following components:

- `list("gene")` data frame with 40 observations on 120 numerical variables.
- `list("lipid")` data frame with 40 observations on 21 numerical variables.
- `list("diet")` factor of 5 levels containing 40 labels for the diet factor.
- `list("genotype")` factor of 2 levels containing 40 labels for the diet factor.
Details

The data sets come from a nutrigenomic study in the mouse (Martin et al., 2007) in which the effects of five regimens with contrasted fatty acid compositions on liver lipids and hepatic gene expression in mice were considered. Two sets of variables were acquired on forty mice:

- **gene**: expressions of 120 genes measured in liver cells, selected (among about 30,000) as potentially relevant in the context of the nutrition study. These expressions come from a nylon macroarray with radioactive labelling;
- **lipid**: concentrations (in percentages) of 21 hepatic fatty acids measured by gas chromatography.

Biological units (mice) were cross-classified according to two factors experimental design (4 replicates):

- **Genotype**: 2-levels factor, wild-type (WT) and PPARα -/- (PPAR).
- **Diet**: 5-levels factor. Oils used for experimental diets preparation were corn and colza oils (50/50) for a reference diet (REF), hydrogenated coconut oil for a saturated fatty acid diet (COC), sunflower oil for an Omega6 fatty acid-rich diet (SUN), linseed oil for an Omega3-rich diet (LIN) and corn/colza/enriched fish oils for the FISH diet (43/43/14).

Value

none

Source

The nutrimouse dataset was provided by Pascal Martin from the Toxicology and Pharmacology Laboratory, National Institute for Agronomic Research, French.

**pca**

*Principal Components Analysis*

Description

Performs a principal components analysis on the given data matrix that can contain missing values. If data are complete `pca` uses Singular Value Decomposition, if there are some missing values, it uses the NIPALS algorithm.
Usage

```r
pca(
  X, 
  ncomp = 2, 
  center = TRUE, 
  scale = FALSE, 
  max.iter = 500, 
  tol = 1e-09, 
  logratio = c("none","CLR","ILR"), 
  ilr.offset = 0.001, 
  V = NULL, 
  multilevel = NULL, 
  verbose.call = FALSE
)
```

Arguments

- **X**: a numeric matrix (or data frame) which provides the data for the principal components analysis. It can contain missing values in which case `center = TRUE` is used as required by the `nipals` function.

- **ncomp**: Integer, if data is complete `ncomp` decides the number of components and associated eigenvalues to display from the `pcasvd` algorithm and if the data has missing values, `ncomp` gives the number of components to keep to perform the reconstitution of the data using the NIPALS algorithm. If `NULL`, function sets `ncomp = min(nrow(X),ncol(X))`.

- **center**: (Default=TRUE) Logical, whether the variables should be shifted to be zero centered. Only set to FALSE if data have already been centered. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to `scale`. If the data contain missing values, columns should be centered for reliable results.

- **scale**: (Default=FALSE) Logical indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with `prcomp` function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to `scale`.

- **max.iter**: Integer, the maximum number of iterations in the NIPALS algorithm.

- **tol**: Positive real, the tolerance used in the NIPALS algorithm.

- **logratio**: (Default='none') one of ('none', 'CLR', 'ILR'). Specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'

- **ilr.offset**: (Default=0.001) When logratio is set to 'ILR', an offset must be input to avoid infinite value after the logratio transform.

- **V**: Matrix used in the logratio transformation if provided.

- **multilevel**: sample information for multilevel decomposition for repeated measurements.
verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

The calculation is done either by a singular value decomposition of the (possibly centered and scaled) data matrix, if the data is complete or by using the NIPALS algorithm if there is data missing. Unlike princomp, the print method for these objects prints the results in a nice format and the plot method produces a bar plot of the percentage of variance explained by the principal components (PCs).

When using NIPALS (missing values), we make the assumption that the first \(\min(\text{ncol}(X), \text{nrow}(X))\) principal components will account for 100% of the explained variance.

Note that scale = TRUE will throw an error if there are constant variables in the data, in which case it’s best to filter these variables in advance.

According to Filzmoser et al., a ILR log ratio transformation is more appropriate for PCA with compositional data. Both CLR and ILR are valid.

Logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through logratio.transfo and withinVariation respectively.

Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset). For ILR transformation and additional offset might be needed.

Value

pca returns a list with class "pca" and "prcomp" containing the following components:

- call: if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessible via this component
- X: The input data matrix, possibly scaled and centered.
- ncomp: The number of principal components used.
- center: The centering used.
- scale: The scaling used.
- names: List of row and column names of data.
- sdev: The eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix or by using NIPALS.
- loadings: A length one list of matrix of variable loadings for X (i.e., a matrix whose columns contain the eigenvectors).
- variates: Matrix containing the coordinate values corresponding to the projection of the samples in the space spanned by the principal components. These are the dimension-reduced representation of observations/samples.
- var.tot: Total variance in the data.
- prop.expl.var: Proportion of variance explained per component after setting possible missing values in the data to zero (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).
The cumulative explained variance for components.

If multilevel, the data matrix with within-group-variation removed.

If multilevel, the provided design.

  signif.threshold = 0.01,
  ...
)
Arguments

object
  object of class inherited from "pls", "plsda", "spls", "splsda" or "mint.splsda".
The function will retrieve some key parameters stored in that object.

... not used

validation
  character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".

folds
  the folds in the Mfold cross-validation. See Details.

progressBar
  by default set to FALSE to output the progress bar of the computation.

nrepeat
  Number of times the Cross-Validation process is repeated. This is an important argument to ensure the estimation of the performance to be as accurate as possible.

dist
  only applies to an object inheriting from "plsda", "splsda" or "mint.splsda" to evaluate the classification performance of the model. Should be a subset of "max.dist", "centroids.dist", "mahalanobis.dist". Default is "all". See predict.

auc
  if TRUE calculate the Area Under the Curve (AUC) performance of the model.

signif.threshold
  numeric between 0 and 1 indicating the significance threshold required for improvement in error rate of the components. Default to 0.01.

cpus
  Number of cpus to use when running the code in parallel.

Details

Procedure. The process of evaluating the performance of a fitted model object is similar for all PLS-derived methods; a cross-validation approach is used to fit the method of object on folds-1 subsets of the data and then to predict on the subset left out. Different measures of performance are available depending on the model. Parameters such as logratio, multilevel, keepX or keepY are retrieved from object.

Parameters. If validation = "Mfold", M-fold cross-validation is performed. folds specifies the number of folds to generate. The folds also can be supplied as a list of vectors containing the indexes defining each fold as produced by split. When using validation = "Mfold", make sure that you repeat the process several times (as the results will be highly dependent on the random splits and the sample size).

If validation = "loo", leave-one-out cross-validation is performed (in that case, there is no need to repeat the process).

Measures of performance. For fitted PLS and sPLS regression models, perf estimates the mean squared error of prediction (MSEP), $R^2$, and $Q^2$ to assess the predictive perfity of the model using M-fold or leave-one-out cross-validation. Note that only the classic, regression and invariant modes can be applied. For sPLS, the MSEP, $R^2$, and $Q^2$ criteria are averaged across all folds. Note that for PLS and sPLS objects, perf is performed on the pre-processed data after log ratio transform and multilevel analysis, if any.

Sparse methods. The sPLS, sPLS-DA and sgccda functions are run on several and different subsets of data (the cross-folds) and will certainly lead to different subset of selected features. Those are summarised in the output features$stable (see output Value below) to assess how often the variables are selected across all folds. Note that for PLS-DA and sPLS-DA objects, perf is performed...
on the original data, i.e. before the pre-processing step of the log ratio transform and multilevel analysis, if any. In addition for these methods, the classification error rate is averaged across all folds.

The mint.sPLS-DA function estimates errors based on Leave-one-group-out cross validation (where each levels of object$study is left out (and predicted) once) and provides study-specific outputs (study.specific.error) as well as global outputs (global.error).

AUROC. For PLS-DA, sPLS-DA, mint.PLS-DA, mint.sPLS-DA, and block.splsda methods: if auc=TRUE, Area Under the Curve (AUC) values are calculated from the predicted scores obtained from the predict function applied to the internal test sets in the cross-validation process, either for all samples or for study-specific samples (for mint models). Therefore we minimise the risk of overfitting. For block.splsda model, the calculated AUC is simply the blocks-combined AUC for each component calculated using auroc.sgccda. See auroc for more details. Our multivariate supervised methods already use a prediction threshold based on distances (see predict) that optimally determine class membership of the samples tested. As such AUC and ROC are not needed to estimate the performance of the model. We provide those outputs as complementary performance measures. See more details in our mixOmics article.

Prediction distances. See details from predict, and also our supplemental material in the mixOmics article.

Repeats of the CV-folds. Repeated cross-validation implies that the whole CV process is repeated a number of times (nrepeat) to reduce variability across the different subset partitions. In the case of Leave-One-Out CV (validation = 'loo'), each sample is left out once (folds = N is set internally) and therefore nrepeat is by default 1.

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

For sgccda objects, we provide weighted measures (e.g. error rate) in which the weights are simply the correlation of the derived components of a given block with the outcome variable Y.

More details about the PLS modes in ?pls.

Value

For PLS and sPLS models, perf produces a list with the following components for every repeat:

- **MSEP**: Mean Square Error Prediction for each Y variable, only applies to object inherited from "pls", and "spls". Only available when in regression (s)PLS.

- **RMSEP**: Root Mean Square Error Prediction for each Y variable, only applies to object inherited from "pls", and "spls". Only available when in regression (s)PLS.

- **R2**: a matrix of $R^2$ values of the Y-variables for models with 1,...,ncomp components, only applies to object inherited from "pls", and "spls". Only available when in regression (s)PLS.

- **Q2**: if Y contains one variable, a vector of $Q^2$ values else a list with a matrix of $Q^2$ values for each Y-variable. Note that in the specific case of an sPLS model, it is better to have a look at the Q2.total criterion, only applies to object inherited from "pls", and "spls". Only available when in regression (s)PLS.
Q2.total  a vector of $Q^2$-total values for models with 1,..., ncomp components, only applies to object inherited from "pls", and "spls". Available in both (s)PLS modes.

RSS  Residual Sum of Squares across all selected features and the components.

PRESS  Predicted Residual Error Sum of Squares across all selected features and the components.

features  a list of features selected across the folds ($stable.X$ and $stable.Y$) for the keepX and keepY parameters from the input object. Note, this will be NULL if using standard (non-sparse) PLS.

cor.tpred, cor.upred  Correlation between the predicted and actual components for X (t) and Y (u)

RSS.tpred, RSS.upred  Residual Sum of Squares between the predicted and actual components for X (t) and Y (u)

error.rate  For PLS-DA and sPLS-DA models, perf produces a matrix of classification error rate estimation. The dimensions correspond to the components in the model and to the prediction method used, respectively. Note that error rates reported in any component include the performance of the model in earlier components for the specified keepX parameters (e.g. error rate reported for component 3 for keepX = 20 already includes the fitted model on components 1 and 2 for keepX = 20). For more advanced usage of the perf function, see www.mixomics.org/methods/spls-da/ and consider using the predict function.

auc  Averaged AUC values over the nrepeat

For mint.splsdla models, perf produces the following outputs:

study.specific.error  A list that gives BER, overall error rate and error rate per class, for each study

global.error  A list that gives BER, overall error rate and error rate per class for all samples

predict  A list of length ncomp that produces the predicted values of each sample for each class

class  A list which gives the predicted class of each sample for each dist and each of the ncomp components. Directly obtained from the predict output.

auc  AUC values

auc.study  AUC values for each study in mint models

For sgccda models, perf produces the following outputs:

error.rate  Prediction error rate for each block of object$X$ and each dist

error.rate.per.class  Prediction error rate for each block of object$X$, each dist and each class

predict  Predicted values of each sample for each class, each block and each component

class  Predicted class of each sample for each block, each dist, each component and each nrepeat
features 
a list of features selected across the folds ($stable.X$ and $stable.Y$) for the keepX and keepY parameters from the input object.

AveragedPredict.class
if more than one block, returns the average predicted class over the blocks (averaged of the Predict output and prediction using the max.dist distance)

AveragedPredict.error.rate
if more than one block, returns the average predicted error rate over the blocks (using the AveragedPredict.class output)

WeightedPredict.class
if more than one block, returns the weighted predicted class over the blocks (weighted average of the Predict output and prediction using the max.dist distance). See details for more info on weights.

WeightedPredict.error.rate
if more than one block, returns the weighted average predicted error rate over the blocks (using the WeightedPredict.class output.)

MajorityVote
if more than one block, returns the majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.

MajorityVote.error.rate
if more than one block, returns the error rate of the MajorityVote output

WeightedVote
if more than one block, returns the weighted majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.

WeightedVote.error.rate
if more than one block, returns the error rate of the WeightedVote output

weights
Returns the weights of each block used for the weighted predictions, for each nrepeat and each fold

choice.ncomp
For supervised models; returns the optimal number of components for the model for each prediction distance using one-sided t-tests that test for a significant difference in the mean error rate (gain in prediction) when components are added to the model. See more details in Rohart et al 2017 Suppl. For more than one block, an optimal ncomp is returned for each prediction framework.

### plot.pca

**Show (s)pca explained variance plots**

#### Description

Show (s)pca explained variance plots

#### Usage

```r
## S3 method for class 'pca'
plot(x, ncomp = NULL, type = "barplot", ...)
```

#### Arguments

- `x` A (s)pca object
- `ncomp` Integer, the number of components
- `type` Character, default "barplot" or any other type available in plot, as "l","b","p"...
- `...` Not used

#### Author(s)

Kim-Anh Lê Cao, Florian Rohart, Leigh Coonan, Al J Abadi

### plotperf

**Plot for model performance for PSLDA analyses**

#### Description

Function to plot classification performance for supervised methods, as a function of the number of components.
Usage

## S3 method for class 'perf.plsda.mthd'
plot(
  x,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("all", "overall", "BER"),
  col,
  xlab = NULL,
  ylab = NULL,
  overlay = c("all", "measure", "dist"),
  legend.position = c("vertical", "horizontal"),
  sd = TRUE,
  ...
)

## S3 method for class 'perf.splsda.mthd'
plot(
  x,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("all", "overall", "BER"),
  col,
  xlab = NULL,
  ylab = NULL,
  overlay = c("all", "measure", "dist"),
  legend.position = c("vertical", "horizontal"),
  sd = TRUE,
  ...
)

## S3 method for class 'perf.mint.plsda.mthd'
plot(
  x,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("all", "overall", "BER"),
  col,
  xlab = NULL,
  ylab = NULL,
  study = "global",
  overlay = c("all", "measure", "dist"),
  legend.position = c("vertical", "horizontal"),
  ...
)

## S3 method for class 'perf.mint.splsda.mthd'
plot(
  x,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("all", "overall", "BER"),
  col,
col,
  xlab = NULL,
  ylab = NULL,
  study = "global",
  overlay = c("all", "measure", "dist"),
  legend.position = c("vertical", "horizontal"),
  ...
)

## S3 method for class 'perf.sgccda.mthd'
plot(
  x,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("all", "overall", "BER"),
  col,
  weighted = TRUE,
  xlab = NULL,
  ylab = NULL,
  overlay = c("all", "measure", "dist"),
  legend.position = c("vertical", "horizontal"),
  sd = TRUE,
  ...
)

Arguments

x an perf.plsda object.
dist prediction method applied in perf for plsda or splsda. See perf.
measure Two misclassification measure are available: overall misclassification error overall or the Balanced Error Rate BER
col character (or symbol) colour to be used, possibly vector. One color per distance dist.
xlab, ylab titles for x and y axes. Typically character strings, but can be expressions (e.g., expression(R^2)).
overlay parameter to overlay graphs; if ‘all’, only one graph is shown with all outputs; if ’measure’, a graph is shown per distance; if ’dist’, a graph is shown per measure.
legend.position position of the legend, one of "vertical" (only one column) or "horizontal" (two columns).
sd If ’nrepeat’ was used in the call to ’perf’, error bar shows the standard deviation if sd=TRUE. For mint objects sd is set to FALSE as the number of repeats is 1.
... Not used.
study Indicates which study-specific outputs to plot. A character vector containing some levels of object$study, "all.partial" to plot all studies or "global" is expected. Default to "global".
weighted plot either the performance of the Majority vote or the Weighted vote.
plot.perf.pls

Details
More details about the prediction distances in ?predict and the supplemental material of the mixOmics article (Rohart et al. 2017). See ?perf for examples.

plot.perf.pls Plot for model performance for PLS analyses

Description
Function to plot performance criteria, such as MSEP, RMSEP, $R^2$, $Q^2$ for s/PLS methods as a function of the number of components.

Usage
## S3 method for class 'perf.pls.mthd'
plot(
  x,
  criterion = "MSEP",
  xlab = "Number of components",
  ylab = NULL,
  LimQ2 = 0.0975,
  LimQ2.col = "grey30",
  sd = NULL,
  pch = 1,
  pch.size = 3,
  cex = 1.2,
  col = color.mixo(1),
  title = NULL,
  ...
)
## S3 method for class 'perf.spls.mthd'
plot(
  x,
  criterion = "MSEP",
  xlab = "Number of components",
  ylab = NULL,
  LimQ2 = 0.0975,
  LimQ2.col = "grey30",
  sd = NULL,
  pch = 1,
  pch.size = 3,
  cex = 1.2,
  col = color.mixo(1),
  title = NULL,
  ...
)

### Arguments

- **x**: an `perf.pls` object.
- **criterion**: character string. What type of validation criterion to plot for `pls` or `spls`. One of "MSEP", "RMSEP", "R2" or "Q2". More measures available for pls2 methods. See `perf`.
- **xlab, ylab**: titles for x and y axes. Typically character strings, but can be expressions (e.g., \(R^2\)).
- **LimQ2**: numeric value. Signification limit for the components in the model. Default is `LimQ2 = 0.0975`.
- **LimQ2.col**: character string specifying the color for the LimQ2 line to be plotted. If "none" the line will not be plotted.
- **sd**: If `nrepeat` was used in the call to `perf`, error bar shows the standard deviation if sd=TRUE. For mint objects sd is set to FALSE as the number of repeats is 1.
- **pch**: Plot character to use.
- **pch.size**: Plot character size to use.
- **cex**: A numeric which adjusts the font size in the plot.
- **col**: Character. Colour to be used for data points.
- **title**: Character, Plot title. Not used by PLS2 feature-wise measure plots.
- **...**: Not used.

### Details

`plot.perf` creates one plot for each response variable in the model, laid out in a multi-panel display. See `?perf` for examples.

### Value

- `none`

plot.rcc

Canonical Correlations Plot

Description

This function provides scree plot of the canonical correlations.

Usage

## S3 method for class 'rcc'
plot(x, type = "barplot", ...)

Arguments

x

object of class inheriting from "rcc".

type

Character, default "barplot" or any other type available in plot, as "l","b","p"...

... Not used

Value

none

Author(s)

Sébastien Déjean, Ignacio González, Al J Abadi

See Also

points, barplot, par.
Examples

data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res <- rcc(X, Y, lambda1 = 0.064, lambda2 = 0.008)

## 'pointplot' type scree
plot(nutri.res) #(default)

## Not run:
plot(nutri.res, pch = 19, cex = 1.2,
col = c(rep("red", 3), rep("darkblue", 18)))

## 'barplot' type scree
plot(nutri.res, type = "barplot")
plot(nutri.res, type = "barplot", density = 20, col = "black")

## End(Not run)

---

plot.tune  
Plot model performance

Description

Function to plot performance criteria, such as classification error rate or correlation of cross-validated components for different models.

Function to plot performance criteria, such as classification error rate or balanced error rate on a tune.splsda result.

Usage

## S3 method for class 'tune.spls'
plot(
x,
  measure = NULL,
  comp = c(1, 2),
  pch = 16,
  cex = 1.2,
  title = NULL,
  size.range = c(3, 10),
  sd = NULL,
  ...
)

## S3 method for class 'tune.block.splsda'
plot(x, sd = NULL, col, ...)
## S3 method for class 'tune.spca'

plot(x, optimal = TRUE, sd = NULL, col = NULL, ...)

## S3 method for class 'tune.spls1'

plot(x, optimal = TRUE, sd = NULL, col, ...)

## S3 method for class 'tune.splsda'

plot(x, optimal = TRUE, sd = NULL, col, ...)

### Arguments

- **x**: an `tune.splsda` object.
- **measure**: Character. Measure used for plotting a `tune.spls` object. One of c('cor', 'RSS').
- **comp**: Integer of length 2 denoting the components to plot.
- **pch**: plot character. A character string or a vector of single characters or integers. See `points` for all alternatives.
- **cex**: numeric character (or symbol) expansion, possibly vector.
- **title**: Plot title.
- **size.range**: Numeric vector of length 2. Range of sizes used in plot.
- **sd**: If 'nrepeat' was used in the call to 'tune.splsda', error bar shows the standard deviation if sd=TRUE
- **...**: Not currently used.
- **col**: character (or symbol) color to be used, possibly vector. One colour per component.
- **optimal**: If TRUE, highlights the optimal keepX per component

### Details

`plot.tune.splsda` plots the classification error rate or the balanced error rate from `x$error.rate`, for each component of the model. A lozenge highlights the optimal number of variables on each component.

`plot.tune.block.splsda` plots the classification error rate or the balanced error rate from `x$error.rate`, for each component of the model. The error rate is ordered by increasing value, the yaxis shows the optimal combination of keepX at the top (e.g. ‘keepX on block 1’ ‘keepX on block 2’ ‘keepX on block 3’)

`plot.tune.spls` plots either the correlation of cross-validated components or the Residual Sum of Square (RSS) values for these components against those from the full model for both t (X components) and u (Y components). The optimal number of features chosen are indicated by squares.

If neither of the `object$test.keepX` or `object$test.keepY` are fixed, a dot plot is produced where a larger size indicates the strength of the measure (higher correlation or lower RSS). Otherwise, the measures are plotted against the number of features selected. In both cases, the colour shows the dispersion of the values across repeated cross validations.
plot.tune.spca plots the correlation of cross-validated components from the tune.spca function with respect to the full model.

plot.tune.splsda plots the classification error rate or the balanced error rate from x$error.rate, for each component of the model. A lozenge highlights the optimal number of variables on each component.

plot.tune.block.splsda plots the classification error rate or the balanced error rate from x$error.rate, for each component of the model. The error rate is ordered by increasing value, the y-axis shows the optimal combination of keepX at the top (e.g. 'keepX on block 1'_'keepX on block 2'_'keepX on block 3')

Value

none

none

plot arguments for pls2 tuning

For tune.spls objects where tuning is performed on both X and Y, arguments 'col.low.sd' and 'col.high.sd' can be used to indicate a low and high sd, respectively. Default to 'blue' & 'red'.

**plotArrow**  
*Arrow sample plot*

**Description**

Represents samples from multiple coordinates to assess the alignment in the latent space.

**Usage**

```r
plotArrow(
    object,
    comp = c(1, 2),
    ind.names = TRUE,
    group = NULL,
    col.per.group = NULL,
    col = NULL,
    ind.names.position = c("start", "end"),
    ind.names.size = 2,
    pch = NULL,
    ```
```r
pch.size = 2,
arrow.alpha = 0.6,
arrow.size = 0.5,
arrow.length = 0.2,
legend = if (is.null(group)) FALSE else TRUE,
legend.title = NULL,
...
)
```

**Arguments**

- **object**: object of class inheriting from `mixOmics`: PLS, sPLS, rCC, rGCCA, sGCCA, sGCCDA
- **comp**: integer vector of length two (or three to 3d). The components that will be used on the horizontal and the vertical axis respectively to project the individuals.
- **ind.names**: either a character vector of names for the individuals to be plotted, or FALSE for no names. If TRUE, the row names of the first (or second) data matrix is used as names (see Details).
- **group**: Factor indicating the group membership for each sample.
- **col.per.group**: character (or symbol) color to be used when 'group' is defined. Vector of the same length as the number of groups.
- **col**: character (or symbol) color to be used, possibly vector.
- **ind.names.position**: One of c('start', 'end') indicating where to show the ind.names. Not used in block analyses, where centroids are used.
- **ind.names.size**: Numeric, sample name size.
- **pch**: plot character. A character string or a named vector of single characters or integers whose names match those of object$variates.
- **pch.size**: Numeric, sample point character size.
- **arrow.alpha**: Numeric between 0 and 1 determining the opacity of arrows.
- **arrow.size**: Numeric, variable arrow head size.
- **arrow.length**: Numeric, length of the arrow head in ‘cm’.
- **legend**: Logical, whether to show the legend if group ! = NULL.
- **legend.title**: Character, the legend title if group ! = NULL.
- **...**: Not currently used. Sample size to display sample names.

**Details**

Graphical of the samples (individuals) is displayed in a superimposed manner where each sample will be indicated using an arrow. The start of the arrow indicates the location of the sample in X in one plot, and the tip the location of the sample in Y in the other plot. Short arrows indicate a strong agreement between the matching data sets, long arrows a disagreement between the matching data sets. The representation space is scaled using the range of coordinates so minimum and maximum values are equal for all blocks. Since the algorithm maximises the covariance of these components, the absolute values do not affect the alignment.
For objects of class "GCCA" and if there are more than 2 blocks, the start of the arrow indicates the centroid between all data sets for a given individual and the tips of the arrows the location of that individual in each block.

Value

A ggplot object

Author(s)

Al J Abadi

# TODO include these customisations into function args  
## custom shapes
plotDiablo

Graphical output for the DIABLO framework

Description

Function to visualise correlation between components from different data sets

Usage

plotDiablo(
    object,
    ncomp = 1,
    legend = TRUE,
    legend.ncol,
    col.per.group = NULL,
    ...
)

## S3 method for class 'sgccda'
plot(x, ...)

p + scale_shape_manual(values = c(
  centroid = 1,
  gene = 2,
  lipid = 3,
  Y = 4
))

## individual representation for objects of class 'sgccda'

# Note: the code differs from above as we use a 'supervised' GCCA analysis

Y = nutrimouse$diet
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid)
design1 = matrix(c(0,1,0,1), ncol = 2, nrow = 2, byrow = TRUE)
nutrimouse.sgccdal <-
  wrapper.sgccda(X = data,
                 Y = Y,
                 design = design1,
                 ncomp = 2,
                 keepX = list(gene = c(10,10), lipid = c(15,15)),
                 scheme = "centroid")

## Default colours correspond to outcome Y
plotArrow(nutrimouse.sgccdal)
plotDiablo

Arguments

- **object.x**: object of class inheriting from "block.splsda".
- **ncomp**: Which component to plot calculated from each data set. Has to be lower than the minimum of object$ncomp.
- **legend**: Logical. Whether the legend should be added. Default is TRUE.
- **legend.ncol**: Number of columns for the legend. Default to \(\min(5,n\text{levels}(x$Y))\).
- **col.per.group**: A named character of colours for each group class representation. Its names must match the levels of object$Y.
- **...**: not used

Details

The function uses a plot.data.frame to plot the component ncomp calculated from each data set to visualise whether DIABLO (block.splsda) is successful at maximising the correlation between each data sets’ component. The lower triangular panel indicated the Pearson’s correlation coefficient, the upper triangular panel the scatter plot.

Value

none

Examples

data('breast.TCGA')
Y = breast.TCGA$data.train$subtype

data = list(mrna = breast.TCGA$data.train$mrna, mirna = breast.TCGA$data.train$mirna, prot = breast.TCGA$data.train$protein)

# set number of component per data set
ncomp = 3

# set number of variables to select, per component and per data set (arbitrarily set)
list.keepX = list(mrna = rep(20, 3), mirna = rep(10,3), prot = rep(10,3))

# DIABLO using a full design where every block is connected
### plotIndiv

**Plot of Individuals (Experimental Units)**

This function provides scatter plots for individuals (experimental units) representation in (sparse)(I)PCA, (regularized)CCA, (sparse)PLS(DA) and (sparse)(R)GCCA(DA).

#### Description

The function `plotIndiv` can be used to visualize individuals (experimental units) in various types of multivariate analysis. It can be applied to objects of classes like `mint.pls` or `block.splsda`.

```r
plotIndiv(object, ...) # S3 method for class 'mint.pls'
```

#### Usage

```r
plotIndiv(object, ...) # S3 method for class 'mint.pls'
```

## Example

```r
BC.diablo = block.splsda(X = data, Y = Y, ncomp = ncomp, keepX = list.keepX, design = 'full')
## default col.per.group
plotDiablo(BC.diablo, ncomp = 1, legend = TRUE, col.per.group = NULL)
## custom col.per.group
col.per.group <- color.mixo(1:3)
names(col.per.group) <- levels(Y)
plotDiablo(BC.diablo, ncomp = 1, legend = TRUE, col.per.group = col.per.group)
```

Arguments

object object of class inherited from any mixOmics: PLS, sPLS, PLS-DA, SPLS-DA, rCC, PCA, sPCA, IPCA, sIPCA, rGCCA, sGCCA, sGCCDA

Optional arguments or type par can be added with style = 'graphics'

comp integer vector of length two (or three to 3d). The components that will be used on the horizontal and the vertical axis respectively to project the individuals.

study Indicates which study-specific outputs to plot. A character vector containing some levels of object$study, "all.partial" to plot all studies or "global" is expected. Default to "global".

rep.space For objects of class "pca", "plsda", "plsda" default is "X-variate". For the objects of class "pls", "rcc" default is a panel plot representing each data sub-space. For objects of class "rgcca" and "sgcca", numerical value(s) indicating the block data set to represent needs to be specified.

group factor indicating the group membership for each sample, useful for ellipse plots. Coded as default for the supervised methods PLS-DA, SPLS-DA, sGCCDA, but needs to be input for the unsupervised methods PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA

col.per.group character (or symbol) color to be used when 'group' is defined. Vector of the same length as the number of groups.

style argument to be set to either 'graphics', 'lattice', 'ggplot2' or '3d' for a style of plotting. Default set to 'ggplot2'. See details. 3d is not available for MINT objects.

ellipse Logical indicating if ellipse plots should be plotted. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA ellipse plot is only be plotted if the argument group is provided. In the PLS-DA, SPLS-DA, sGCCDA supervised object, by default the ellipse will be plotted accoding to the outcome Y.

ellipse.level Numerical value indicating the confidence level of ellipse being plotted when ellipse =TRUE (i.e. the size of the ellipse). The default is set to 0.95, for a 95% region.

centroid Logical indicating whether centroid points should be plotted. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA the centroid will only be plotted if the argument group is provided. The centroid
will be calculated based on the group categories. In the supervised objects PLS-DA, SPLS-DA, sGCCDA the centroid will be calculated according to the outcome $Y$.

**star**
Logical indicating whether a star plot should be plotted, with arrows starting from the centroid (see argument centroid, and ending for each sample belonging to each group or outcome. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA star plot is only be plotted if the argument group is provided. In the supervised objects PLS-DA, SPLS-DA, sGCCDA the star plot is plotted according to the outcome $Y$.

**title**
set of characters indicating the title plot.

**subtitle**
subtitle for each plot, only used when several block or study are plotted.

**legend**
Logical. Whether the legend should be added. Default is FALSE.

**X.label**
x axis titles.

**Y.label**
y axis titles.

**abline**
should the vertical and horizontal line through the center be plotted? Default set to FALSE

**xlim, ylim**
numeric list of vectors of length 2 and length =length(blocks), giving the x and y coordinates ranges.

**col**
character (or symbol) color to be used, possibly vector.

**cex**
numeric character (or symbol) expansion, possibly vector.

**pch**
plot character. A character string or a vector of single characters or integers. See `points` for all alternatives.

**layout**
layout parameter passed to mfrow. Only used when study is not "global"

**size.title**
size of the title

**size.subtitle**
size of the subtitle

**size.xlabel**
size of xlabel

**size.ylabel**
size of ylabel

**size.axis**
size of the axis

**size.legend**
size of the legend

**size.legend.title**
size of the legend title

**legend.title**
title of the legend

**legend.position**
position of the legend, one of "bottom", "left", "top" and "right".

**point.lwd**
1wd of the points, used when ind.names = FALSE

**background**
color the background by the predicted class, see `background.predict`.

**ind.names**
either a character vector of names for the individuals to be plotted, or FALSE for no names. If TRUE, the row names of the first (or second) data matrix is used as names (see Details).

**Z.label**
z axis titles (when style = '3d').
plotIndiv

pch.levels  Only used when pch is different from col or col.per.group, i.e. when pch creates a second factor. Only used for the legend.
alpha  Semi-transparent colors (0 < ‘alpha’ < 1)
axes.box  for style ‘3d’, argument to be set to either ‘axes’, ‘box’, ‘bbox’ or ‘all’, defining the shape of the box.
legend.title.pch  title of the second legend created by pch, if any.
blocks  integer value or name(s) of block(s) to be plotted using the GCCA module. "average" and "weighted.average" will create average and weighted average plots, respectively. See details and examples.

Details

plotIndiv method makes scatter plot for individuals representation depending on the subspace of projection. Each point corresponds to an individual.

If ind.names=TRUE and row names is NULL, then ind.names=1:n, where n is the number of individuals. Also, if pch is an input, then ind.names is set to FALSE as we do not show both names and shapes.

plotIndiv can have a two layers legend. This is especially convenient when you have two grouping factors, such as a gender effect and a study effect, and you want to highlight both simultaneously on the graphical output. A first layer is coded by the group factor, the second by the pch argument. When pch is missing, a single layer legend is shown. If the group factor is missing, the col argument is used to create the grouping factor group. When a second grouping factor is needed and added via pch, pch needs to be a vector of length the number of samples. In the case where pch is a vector or length the number of groups, then we consider that the user wants a different pch for each level of group. This leads to a single layer legend and we merge col and pch. In the similar case where pch is a single value, then this value is used to represent all samples. See examples below for object of class plsda and splsda.

In the specific case of a single ‘omics supervised model (plsda, splsda), users can overlay prediction results to sample plots in order to visualise the prediction areas of each class, via the background input parameter. Note that this functionality is only available for models with less than 2 components as the surfaces obtained for higher order components cannot be projected onto a 2D representation in a meaningful way. For more details, see background.predict

The argument block = ‘average’ averages the components from all blocks to produce a consensus plot. The argument block=‘weighted.average’ is a weighted average of the components according to their correlation with the outcome Y.

For customized plots (i.e. adding points, text), use the style = ‘graphics’ (default is ggplot2).

Note: the ellipse options were borrowed from the ellipse.

plotIndiv(nutrimouse.sgccda1, blocks = "average", group = nutrimouse$diet)

# include the weighted average plot (average of components weighted by
# correlation of each dataset with Y)
plotIndiv(nutrimouse.sgccda1, blocks = c("average", "weighted.average"), group = nutrimouse$diet)
## End(Not run)

### Description

This function provides a horizontal bar plot to visualise loading vectors. For discriminant analysis, it provides visualisation of highest or lowest mean/median value of the variables with color code corresponding to the outcome of interest.

### Usage

```r
plotLoadings(object, ...)
```

```r

**Arguments**

- **object**: object
- **...**: not used.
- **block**: A single value indicating which block to consider in a sgccda object.
- **comp**: integer value indicating the component of interest from the object.
- **col**: color used in the barplot, only for object from non Discriminant analysis
- **ndisplay**: integer indicating how many of the most important variables are to be plotted (ranked by decreasing weights in each PLS-component). Useful to lighten a graph.
- **size.name**: A numerical value giving the amount by which plotting the variable name text should be magnified or reduced relative to the default.
- **name.var**: A character vector indicating the names of the variables. The names of the vector should match the names of the input data, see example.
name.var.complete
Logical. If name.var is supplied with some empty names, name.var.complete allows you to use the initial variable names to complete the graph (from colnames(X)). Default to FALSE.

title
A set of characters to indicate the title of the plot. Default value is NULL.
subtitle
subtitle for each plot, only used when several block or study are plotted.
size.title
size of the title
size.subtitle
size of the subtitle
layout
Vector of two values (rows,cols) that indicates the layout of the plot. If layout is provided, the remaining empty subplots are still active
border
Argument from barplot: indicates whether to draw a border on the barplot.
xlim
Argument from barplot: limit of the x-axis. When plotting several block, a matrix is expected where each row is the xlim used for each of the blocks.
contrib
a character set to 'max' or 'min' indicating if the color of the bar should correspond to the group with the maximal or minimal expression levels / abundance.
method
a character set to 'mean' or 'median' indicating the criterion to assess the contribution. We recommend using median in the case of count or skewed data.
plot
Logical indicating of the plot should be output. If set to FALSE the user can extract the contribution matrix, see example. Default value is TRUE.
show.ties
Logical. If TRUE then tie groups appear in the color set by col.ties, which will appear in the legend. Ties can happen when dealing with count data type. By default set to TRUE.
col.ties
Color corresponding to ties, only used if show.ties=TRUE and ties are present.
size.legend
A numerical value giving the amount by which plotting the legend text should be magnified or reduced relative to the default.
legend
Logical indicating if the legend indicating the group outcomes should be added to the plot. Default value is TRUE.
legend.color
A color vector of length the number of group outcomes. See examples.
legend.title
A set of characters to indicate the title of the legend. Default value is NULL.
study
Indicates which study are to be plotted. A character vector containing some levels of object$study, "all.partial" to plot all studies or "global" is expected.

Details
The contribution of each variable for each component (depending on the object) is represented in a barplot where each bar length corresponds to the loading weight (importance) of the feature. The loading weight can be positive or negative.

For discriminant analysis, the color corresponds to the group in which the feature is most 'abundant'. Note that this type of graphical output is particularly insightful for count microbial data - in that latter case using the method = 'median' is advised. Note also that if the parameter contrib is not provided, plots are white.

For MINT analysis, study="global" plots the global loadings while partial loadings are plotted when study is a level of object$study. Since variable selection in MINT is performed at the global level, only the selected variables are plotted for the partial loadings even if the partial loadings are not sparse. See references. Importantly for multi plots, the legend accounts for one subplot in the layout design.
Value

Invisibly returns a data.frame containing the contribution of features on each component. For supervised models the contributions for each class is also specified. See details.

### Description

Plots the standardised values (after centring and/or scaling) for the selected variables for a given block on a given component. Only applies to block.splsda or block.spls.

### Usage

```r
plotMarkers(
  object, block, markers = NULL, comp = 1, group = NULL,
  col.per.group = NULL, global = FALSE, title = NULL,
  violin = TRUE, boxplot.width = NULL, violin.width = 0.9
)
```

### Arguments

- **object**: An object of class block.splsda or block.spls
- **block**: Name or index of the block to use
- **markers**: Character or integer, only include these markers. If integer, the top 'markers' features are shown
- **comp**: Integer, the component to use
- **group**: Factor, the grouping variable (only required for block.spls objects)
- **col.per.group**: Character (or symbol) color to be used when 'group' is defined. Vector of the same length as the number of groups.
- **global**: Logical indicating whether to show the global plots (TRUE) or segregate by feature (FALSE). Only available when object$scale=TRUE
- **title**: The plot title
- **violin**: (if global = FALSE) Logical indicating whether violin plots should also be shown
- **boxplot.width**: Numeric, adjusts the width of the box plots
- **violin.width**: Numeric, adjusts the width of the violin plots
plotVar

Description

This function provides variables representation for (regularized) CCA, (sparse) PLS regression, PCA and (sparse) Regularized generalised CCA.

Usage

plotVar(
  object,
  comp = NULL,
  comp.select = comp,
  plot = TRUE,
  var.names = NULL,
  blocks = NULL,
  X.label = NULL,
  Y.label = NULL,
  Z.label = NULL,
  abline = TRUE,
  col,
  cex,
  pch,
  font,
  cutoff = 0,
  rad.in = 0.5,
  title = "Correlation Circle Plot",
  legend = FALSE,
  legend.title = "Block",
  style = "ggplot2",
  overlap = TRUE,
  axes.box = "all",
  label.axes.box = "both"
)
Arguments

- **object**: object of class inheriting from "rcc", "pls", "plsda", "spls", "splsda", "pca" or "spca".

- **comp**: integer vector of length two. The components that will be used on the horizontal and the vertical axis respectively to project the variables. By default, comp=c(1,2) except when style='3d', comp=c(1:3)

- **comp.select** for the sparse versions, an input vector indicating the components on which the variables were selected. Only those selected variables are displayed. By default, comp.select=comp

- **plot** if TRUE (the default) then a plot is produced. If not, the summaries which the plots are based on are returned.

- **var.names** either a character vector of names for the variables to be plotted, or FALSE for no names. If TRUE, the col names of the first (or second) data matrix is used as names.

- **blocks** for an object of class "rgcca" or "sgcca", a numerical vector indicating the block variables to display.

- **X.label** x axis titles.

- **Y.label** y axis titles.

- **Z.label** z axis titles (when style = '3d').

- **abline** should the vertical and horizontal line through the center be plotted? Default set to FALSE

- **col** character or integer vector of colors for plotted character and symbols, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See Details.

- **cex** numeric vector of character expansion sizes for the plotted character and symbols, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables).

- **pch** plot character. A vector of single characters or integers, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See points for all alternatives.

- **font** numeric vector of font to be used, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See par for details.

- **cutoff** numeric between 0 and 1. Variables with correlations below this cutoff in absolute value are not plotted (see Details).

- **rad.in** numeric between 0 and 1, the radius of the inner circle. Defaults to 0.5.

- **title** character indicating the title plot.

- **legend** Logical when more than 3 blocks. Can be a character vector when one or 2 blocks to customize the legend. See examples. Default is FALSE.

- **legend.title** title of the legend

- **style** argument to be set to either 'graphics', 'lattice', 'ggplot2' or '3d' for a style of plotting.
overlap Logical. Whether the variables should be plotted in one single figure. Default is TRUE.

axes.box for style '3d', argument to be set to either 'axes', 'box', 'bbox' or 'all', defining the shape of the box.

label.axes.box for style '3d', argument to be set to either 'axes', 'box', 'both', indicating which labels to print.

Details

plotVar produce a "correlation circle", i.e. the correlations between each variable and the selected components are plotted as scatter plot, with concentric circles of radius one et radius given by rad.in. Each point corresponds to a variable. For (regularized) CCA the components correspond to the equiangular vector between \(X\)- and \(Y\)-variates. For (sparse) PLS regression mode the components correspond to the \(X\)-variates. If mode is canonical, the components for \(X\) and \(Y\) variables correspond to the \(X\)- and \(Y\)-variates respectively.

For \(p\)ls\(d\)a and \(s\)pls\(d\)a objects, only the \(X\) variables are represented.

For \(s\)pls and \(s\)pls\(d\)a objects, only the \(X\) and \(Y\) variables selected on dimensions comp are represented.

The arguments col, pch, cex and font can be either vectors of length two or a list with two vector components of length \(p\) and \(q\) respectively, where \(p\) is the number of \(X\)-variables and \(q\) is the number of \(Y\)-variables. In the first case, the first and second component of the vector determine the graphics attributes for the \(X\)- and \(Y\)-variables respectively. Otherwise, multiple arguments values can be specified so that each point (variable) can be given its own graphic attributes. In this case, the first component of the list correspond to the \(X\) attributs and the second component correspond to the \(Y\) attributs. Default values exist for this arguments.

Value

A list containing the following components:

- \(x\) a vector of coordinates of the variables on the x-axis.
- \(y\) a vector of coordinates of the variables on the y-axis.
- \(Block\) the data block name each variable belongs to.
- \(names\) the name of each variable, matching their coordinates values.

## pls

### Partial Least Squares (PLS) Regression

#### Description
Function to perform Partial Least Squares (PLS) regression.

#### Usage

```r
pls(
  X,
  Y,
  ncomp = 2,
  scale = TRUE,
  mode = c("regression", "canonical", "invariant", "classic"),
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  logratio = "none",
  multilevel = NULL,
)```

---

**pls**

Partial Least Squares (PLS) Regression

**Description**

Function to perform Partial Least Squares (PLS) regression.

**Usage**

```r
pls(
  X,
  Y,
  ncomp = 2,
  scale = TRUE,
  mode = c("regression", "canonical", "invariant", "classic"),
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  logratio = "none",
  multilevel = NULL,
)```
```r
all.outputs = TRUE,
verbose.call = FALSE
)
```

**Arguments**

- **X**
  - numeric matrix of predictors with the rows as individual observations. missing values (NAs) are allowed.

- **Y**
  - numeric matrix of response(s) with the rows as individual observations matching X. missing values (NAs) are allowed.

- **ncomp**
  - Positive Integer. The number of components to include in the model. Default to 2.

- **scale**
  - Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE).

- **mode**
  - Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

- **tol**
  - Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

- **max.iter**
  - Integer, the maximum number of iterations. Default to 100.

- **near.zero.var**
  - Logical, see the internal `nearZeroVar` function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

- **logratio**
  - Character, one of ('none','CLR') specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'. See ?logratio.transfo for details.

- **multilevel**
  - Numeric, design matrix for repeated measurement analysis, where multilevel decomposition is required. For a one factor decomposition, the repeated measures on each individual, i.e. the individuals ID is input as the first column. For a 2 level factor decomposition then 2nd AND 3rd columns indicate those factors. See examplesin ?spls.

- **all.outputs**
  - Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

- **verbose.call**
  - Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

**Details**

`pls` function fit PLS models with 1, ..., ncomp components. Multi-response models are fully supported. The X and Y datasets can contain missing values.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References). Different modes relate on how the Y matrix is deflated across the iterations of the algorithms - i.e. the different components.
- Regression mode: the Y matrix is deflated with respect to the information extracted/modelled from the local regression on X. Here the goal is to predict Y from X (Y and X play an asymmetric role). Consequently the latent variables computed to predict Y from X are different from those computed to predict X from Y.

- Canonical mode: the Y matrix is deflated to the information extracted/modelled from the local regression on Y. Here X and Y play a symmetric role and the goal is similar to a Canonical Correlation type of analysis.

- Invariant mode: the Y matrix is not deflated

- Classic mode: is similar to a regression mode. It gives identical results for the variates and loadings associated to the X data set, but differences for the loadings vectors associated to the Y data set (different normalisations are used). Classic mode is the PLS2 model as defined by Tenenhaus (1998), Chap 9.

Note that in all cases the results are the same on the first component as deflation only starts after component 1.

**Value**

`pls` returns an object of class "pls", a list that contains the following components:

- `call`: if `verbose.call = FALSE`, then just the function call is returned. If `verbose.call = TRUE` then all the inputted values are accessible via this component

- `X`: the centered and standardized original predictor matrix.

- `Y`: the centered and standardized original response vector or matrix.

- `ncomp`: the number of components included in the model.

- `mode`: the algorithm used to fit the model.

- `variates`: list containing the variates.

- `loadings`: list containing the estimated loadings for the X and Y variates. The loading weights multiplied with their associated deflated (residual) matrix gives the variate.

- `loadings.stars`: list containing the estimated weighted loadings for the X and Y variates. The loading weights are projected so that when multiplied with their associated original matrix we obtain the variate.

- `names`: list containing the names to be used for individuals and variables.

- `tol`: the tolerance used in the iterative algorithm, used for subsequent S3 methods

- `iter`: Number of iterations of the algorithm for each component

- `max.iter`: the maximum number of iterations, used for subsequent S3 methods

- `nzv`: list containing the zero- or near-zero predictors information.

- `scale`: whether scaling was applied per predictor.

- `logratio`: whether log ratio transformation for relative proportion data was applied, and if so, which type of transformation.

- `prop_expl_var`: The proportion of the variance explained by each variate / component divided by the total variance in the data (after removing the possible missing values) using the definition of 'redundancy'. Note that contrary to PCA, this amount
may not decrease in the following components as the aim of the method is not to maximise the variance, but the covariance between data sets (including the dummy matrix representation of the outcome variable in case of the supervised approaches).

**input.X** numeric matrix of predictors in X that was input, before any scaling / logratio / multilevel transformation.

**mat.c** matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.

**defl.matrix** residual matrices X for each dimension.

**missing values**

The estimation of the missing values can be performed using the `impute.nipals` function. Otherwise, missing values are handled by element-wise deletion in the `pls` function without having to delete the rows with missing data.

**multilevel**

Multilevel (s)PLS enables the integration of data measured on two different data sets on the same individuals. This approach differs from multilevel sPLS-DA as the aim is to select subsets of variables from both data sets that are highly positively or negatively correlated across samples. The approach is unsupervised, i.e. no prior knowledge about the sample groups is included.

**logratio and multilevel**

logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

## End(Not run)

---

plsdas Partial Least Squares Discriminant Analysis (PLS-DA).

Description

Function to perform standard Partial Least Squares regression to classify samples.

Usage

plsdas(
  X,
  Y,
  ncomp = 2,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  logratio = c("none", "CLR"),
  multilevel = NULL,
  all.outputs = TRUE
)

Arguments

X numeric matrix of predictors with the rows as individual observations. missing values (NAs) are allowed.
Y a factor or a class vector for the discrete outcome.
ncomp Positive Integer. The number of components to include in the model. Default to 2.
scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
**tol**
Positive numeric used as convergence criteria/tolerance during the iterative process. Default to $1e^{-06}$.

**max.iter**
Integer, the maximum number of iterations. Default to 100.

**near.zero.var**
Logical, see the internal `nearZeroVar` function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

**logratio**
Character, one of (‘none’,‘CLR’) specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'. See `logratio.transfo` for details.

**multilevel**
Sample information for multilevel decomposition for repeated measurements. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples in `?splsda`.

**all.outputs**
Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

**Details**

`plsda` function fit PLS models with 1, ..., `ncomp` components to the factor or class vector `Y`. The appropriate indicator matrix is created.

Logratio transformation and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively. Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset).

The type of deflation used is 'regression' for discriminant algorithms. i.e. no deflation is performed on `Y`.

**Value**
`plsda` returns an object of class "`plsda"", a list that contains the following components:

- **X**
  the centered and standardized original predictor matrix.

- **Y**
  the centered and standardized indicator response vector or matrix.

- **ind.mat**
  the indicator matrix.

- **ncomp**
  the number of components included in the model.

- **variates**
  list containing the `X` and `Y` variates.

- **loadings**
  list containing the estimated loadings associated to each component/variate. The loading weights multiplied with the deflated (residual) matrix gives the variate.

- **loadings.stars**
  list containing the estimated loadings associated to each component/variate. The loading weights are projected so that when multiplied with the original matrix we obtain the variate.

- **names**
  list containing the names to be used for individuals and variables.

- **nzv**
  list containing the zero- or near-zero predictors information.

- **tol**
  the tolerance used in the iterative algorithm, used for subsequent S3 methods

- **max.iter**
  the maximum number of iterations, used for subsequent S3 methods
iter  Number of iterations of the algorithm for each component
prop_expl_var  The proportion of the variance explained by each variate / component divided by the total variance in the data (after removing the possible missing values) using the definition of ‘redundancy’. Note that contrary to PCA, this amount may not decrease in the following components as the aim of the method is not to maximise the variance, but the covariance between data sets (including the dummy matrix representation of the outcome variable in case of the supervised approaches).
mat.c  matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
defl.matrix  residual matrices X for each dimension.

---

**predict**

*Predict Method for (mint).(block).(s)pls(da) methods*

### Description

Predicted values based on PLS models. New responses and variates are predicted using a fitted model and a new matrix of observations.

### Usage

#### # S3 method for class 'mixopls'

predict(object, newdata, study.test, dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"), multilevel = NULL, ...)

#### # S3 method for class 'mixospls'

predict(object, newdata, study.test, dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"), multilevel = NULL, ...)

#### # S3 method for class 'mint.splsd'

call object, newdata, study.test, dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"), multilevel = NULL, ...
## S3 method for class 'block.pls'

predict(
  object,
  newdata,
  study.test,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  multilevel = NULL,
  ...
)

## S3 method for class 'block.spls'

predict(
  object,
  newdata,
  study.test,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  multilevel = NULL,
  ...
)

### Arguments

**object**
- object of class inheriting from "(mint).(block).(s)pls(da)".

**newdata**
- data matrix in which to look for explanatory variables to be used for prediction. Please note that this method does not perform multilevel decomposition or log ratio transformations, which need to be processed beforehand.

**study.test**
- For MINT objects, grouping factor indicating which samples of newdata are from the same study. Overlap with object$study are allowed.

**dist**
- distance to be applied for discriminant methods to predict the class of new data, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details). Defaults to "all".

**multilevel**
- Design matrix for multilevel analysis (for repeated measurements). A numeric matrix or data frame. For a one level factor decomposition, the input is a vector indicating the repeated measures on each individual, i.e. the individuals ID. For a two level decomposition with splsda models, the two factors are included in Y. Finally for a two level decomposition with spls models, 2nd AND 3rd columns in design indicate those factors (see example in ?splsda and ?spls).

... not used currently.

### Details

predict produces predicted values, obtained by evaluating the PLS-derived methods, returned by (mint).(block).(s)pls(da) in the frame newdata. Variates for newdata are also returned. Please note that this method performs multilevel decomposition and/or log ratio transformations if needed (multilevel is an input parameter while logratio is extracted from object).
Different prediction distances are proposed for discriminant analysis. The reason is that our supervised models work with a dummy indicator matrix of \( Y \) to indicate the class membership of each sample. The prediction of a new observation results in either a predicted dummy variable (output \texttt{object$predict} \text{,} \text{or a predicted variate (output object$variates}) \text{. Therefore, an appropriate distance needs to be applied to those predicted values to assign the predicted class} \text{. We propose distances such as \textquote{maximum distance} for the predicted dummy variables, \textquote{Mahalanobis distance} and \textquote{Centroids distance} for the predicted variates.}

\textquote{max.dist} is the simplest method to predict the class of a test sample. For each new individual, the class with the largest predicted dummy variable is the predicted class. This distance performs well in single data set analysis with multiclass problems (PLS-DA).

\textquote{centroids.dist} allocates to the new observation the class that minimizes the distance between the predicted score and the centroids of the classes calculated on the latent components or variates of the trained model.

\textquote{mahalanobis.dist} allocates the new sample the class defined as the centroid distance, but using the Mahalanobis metric in the calculation of the distance.

In practice we found that the centroid-based distances (\textquote{centroids.dist} and \textquote{mahalanobis.dist}), and specifically the Mahalanobis distance led to more accurate predictions than the maximum distance for complex classification problems and N-integration problems (block.splsda). The centroid distances consider the prediction in dimensional space spanned by the predicted variates, while the maximum distance considers a single point estimate using the predicted scores on the last dimension of the model. The user can assess the different distances, and choose the prediction distance that leads to the best performance of the model, as highlighted from the tune and perf outputs.

More (mathematical) details about the prediction distances are available in the supplemental of the mixOmics article (Rohart et al 2017).

For a visualisation of those prediction distances, see \texttt{background.predict} that overlays the prediction area in \texttt{plotIndiv} for a sPLS-DA object.

Allocates the individual \( x \) to the class of \( Y \) minimizing \( \text{dist}(\text{x-vari} \text{ate}, G_l) \), where \( G_l, l = 1, ..., L \) are the centroids of the classes calculated on the \( X \)-variates of the model. \textquote{mahalanobis.dist} allocates the individual \( x \) to the class of \( Y \) as in \textquote{centroids.dist} but by using the Mahalanobis metric in the calculation of the distance.

For MINT objects, the \texttt{study.test} argument is required and provides the grouping factor of \texttt{newdata}.

For multi block analysis (thus block objects), \texttt{newdata} is a list of matrices whose names are a subset of \texttt{names(object$X)} and missing blocks are allowed. Several predictions are returned, either for each block or for all blocks. For non discriminant analysis, the predicted values (\texttt{predict}) are returned for each block and these values are combined by average (\texttt{AveragedPredict}) or weighted average (\texttt{WeightedPredict}), using the weights of the blocks that are calculated as the correlation between a block’s components and the outcome’s components.

For discriminant analysis, the predicted class is returned for each block (\texttt{class}) and each distance (\texttt{dist}) and these predictions are combined by majority vote (\texttt{MajorityVote}) or weighted majority vote (\texttt{WeightedVote}), using the weights of the blocks that are calculated as the correlation between a block’s components and the outcome’s components. NA means that there is no consensus among the block. For PLS-DA and sPLS-DA objects, the prediction area can be visualised in \texttt{plotIndiv} via the \texttt{background.predict} function.
predict produces a list with the following components:

- **predict**: predicted response values. The dimensions correspond to the observations, the response variables and the model dimension, respectively. For a supervised model, it corresponds to the predicted dummy variables.
- **variates**: matrix of predicted variates.
- **B.hat**: matrix of regression coefficients (without the intercept).
- **AveragedPredict**: if more than one block, returns the average predicted values over the blocks (using the predict output).
- **WeightedPredict**: if more than one block, returns the weighted average of the predicted values over the blocks (using the predict and weights outputs).
- **class**: predicted class of newdata for each 1,...,ncomp components.
- **MajorityVote**: if more than one block, returns the majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.
- **WeightedVote**: if more than one block, returns the weighted majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.
- **weights**: Returns the weights of each block used for the weighted predictions, for each nrepeat and each fold.
- **centroids**: matrix of coordinates for centroids.
- **dist**: type of distance requested.
- **vote**: majority vote result for multi block analysis (see details above).

# example with block.splsda=diablo=sgccda and a missing block
res.train = block.splsda(X=list(gene=gene.train,lipid=lipid.train),Y=Y.train,
ncomp=3,keepX=list(gene=c(10,10,10),lipid=c(5,5,5)))
test.predict = predict(res.train, newdata=data.test[2], method = "max.dist")

## example with mint.splsda
data(stemcells)

# training set
ind.test = which(stemcells$study == "3")
gene.train = stemcells$gene[-ind.test,]
Y.train = stemcells$celltype[-ind.test]
study.train = factor(stemcells$study[-ind.test])

# test set
gene.test = stemcells$gene[ind.test,]
Y.test = stemcells$celltype[ind.test]
study.test = factor(stemcells$study[ind.test])

res = mint.splsda(X = gene.train, Y = Y.train, ncomp = 3, keepX = c(10, 5, 15),
study = study.train)
pred = predict(res, newdata = gene.test, study.test = study.test)
data.frame(Truth = Y.test, prediction = pred$class$max.dist)

## End(Not run)
Description

Produce print methods for class "rcc", "pls", "spls", "pca", "rgcca", "sgcca" and "summary".

Usage

```r
## S3 method for class 'mixo_pls'
print(x, ...)

## S3 method for class 'mint.pls'
print(x, ...)

## S3 method for class 'mixo_plsda'
print(x, ...)

print(x, ...)

## S3 method for class 'predict'
print(x, ...)

print

Arguments

x  object of class inherited from "rcc", "pls", "spls", "pca", "spca", "rgcca", "sgcca" or "summary".
...  not used currently.

Details

print method for "rcc", "pls", "spls", "pca", "rgcca", "sgcca" class, returns a description of the x object including: the function used, the regularization parameters (if x of class "rcc"), the (s)PLS algorithm used (if x of class "pls" or "spls"), the samples size, the number of variables selected on each of the sPLS components (if x of class "spls") and the available components of the object.

print method for "summary" class, gives the (s)PLS algorithm used (if x of class "pls" or "spls"), the number of variates considered, the canonical correlations (if x of class "rcc"), the number of variables selected on each of the sPLS components (if x of class "spls") and the available components for Communalities Analysis, Redundancy Analysis and Variable Importance in the Projection (VIP).

Value

none

Examples

```r
## print for objects of class 'rcc'
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res <- rcc(X, Y, ncomp = 3, lambda1 = 0.064, lambda2 = 0.008)
print(nutri.res)

## Not run:
## print for objects of class 'summary'
more <- summary(nutri.res, cutoff = 0.65)
print(more)

## print for objects of class 'pls'
data(linnerud)
X <- linnerud$exercise
Y <- linnerud$physiological
linn.pls <- pls(X, Y)
print(linn.pls)
```
## print for objects of class 'spls'
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic
toxicity.spls <- spls(X, Y, ncomp = 3, keepX = c(50, 50, 50),
                    keepY = c(10, 10, 10))
print(toxicity.spls)

## End(Not run)

---

### rcc

**Regularized Canonical Correlation Analysis**

#### Description

The function performs the regularized extension of the Canonical Correlation Analysis to seek correlations between two data matrices.

#### Usage

```r
ccc(
  X,
  Y,
  ncomp = 2,
  method = c("ridge", "shrinkage"),
  lambda1 = 0,
  lambda2 = 0,
  verbose.call = FALSE
)
```

#### Arguments

- **X**: numeric matrix or data frame \((n \times p)\), the observations on the \(X\) variables. NAs are allowed.
- **Y**: numeric matrix or data frame \((n \times q)\), the observations on the \(Y\) variables. NAs are allowed.
- **ncomp**: the number of components to include in the model. Default to 2.
- **method**: One of "ridge" or "shrinkage". If "ridge", \(\lambda_1\) and \(\lambda_2\) need to be supplied (see also our function tune.ccc); if "shrinkage", parameters are directly estimated with Strimmer’s formula, see below and reference.
- **lambda1, lambda2**: a non-negative real. The regularization parameter for the \(X\) and \(Y\) data. Defaults to \(\lambda_1 = \lambda_2 = 0\). Only used if method="ridge"
- **verbose.call**: Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.
Details

The main purpose of Canonical Correlations Analysis (CCA) is the exploration of sample correlations between two sets of variables $X$ and $Y$ observed on the same individuals (experimental units) whose roles in the analysis are strictly symmetric.

The cancor function performs the core of computations but additional tools are required to deal with data sets highly correlated (nearly collinear), data sets with more variables than units by example. The rcc function, the regularized version of CCA, is one way to deal with this problem by including a regularization step in the computations of CCA. Such a regularization in this context was first proposed by Vinod (1976), then developed by Leurgans et al. (1993). It consists in the regularization of the empirical covariances matrices of $X$ and $Y$ by adding a multiple of the matrix identity, that is, $\text{Cov}(X) + \lambda_1 I$ and $\text{Cov}(Y) + \lambda_2 I$.

When $\lambda_1 = 0$ and $\lambda_2 = 0$, rcc performs a classical CCA, if possible (i.e. when $n > p + q$).

The shrinkage estimates method = "shrinkage" can be used to bypass tune.rcc to choose the shrinkage parameters - which can be long and costly to compute with very large data sets. Note that both functions tune.rcc (which uses cross-validation) and the shrinkage parameters (which uses the formula from Schafer and Strimmer, see the corpcor package estimate.lambda) may output different results.

Note: when method = "shrinkage" the parameters are estimated using estimate.lambda from the corpcor package. Data are then centered to calculate the regularised variance-covariance matrices in rcc.

Missing values are handled in the function, except when using method = "shrinkage". In that case the estimation of the missing values can be performed by the reconstitution of the data matrix using the nipals function.

Value

rcc returns a object of class "rcc", a list that contains the following components:

- **X**: the original $X$ data.
- **Y**: the original $Y$ data.
- **cor**: a vector containing the canonical correlations.
- **lambda**: a vector containing the regularization parameters whether those were input if ridge method or directly estimated with the shrinkage method.
- **loadings**: list containing the estimated coefficients used to calculate the canonical variates in $X$ and $Y$.
- **variates**: list containing the canonical variates.
- **names**: list containing the names to be used for individuals and variables.
- **prop_expl_var**: Proportion of the explained variance of derived components, after setting possible missing values to zero.
- **call**: if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessible via this component.

Examples

```r
## Classic CCA
data(linnerud)
X <- linnerud$exercise
Y <- linnerud$physiological
linn.res <- rcc(X, Y)

## Not run:
## Regularized CCA
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res1 <- rcc(X, Y, ncomp = 3, lambda1 = 0.064, lambda2 = 0.008)

## using shrinkage parameters
nutri.res2 <- rcc(X, Y, ncomp = 3, method = 'shrinkage')
nutri.res2$lambda # the shrinkage parameters

## End(Not run)
```
selectVar  

Output of selected variables

**Description**

This function outputs the selected variables on each component for the sparse versions of the approaches (was also generalised to the non sparse versions for our internal functions).

**Usage**

```r
selectVar(...)
```

```r
## S3 method for class 'mixo_pls'
selectVar(object, comp = 1, block = NULL, ...)
```

```r
## S3 method for class 'mixo_spls'
selectVar(object, comp = 1, block = NULL, ...)
```

```r
## S3 method for class 'pca'
selectVar(object, comp = 1, block = NULL, ...)
```

```r
## S3 method for class 'sgcca'
selectVar(object, comp = 1, block = NULL, ...)
```

```r
## S3 method for class 'rgcca'
selectVar(object, comp = 1, block = NULL, ...)
```

**Arguments**

- `...` other arguments.
- `object` object of class inherited from `"pls"`, `"spls"`, `"plsd"`, `"plsda"`, `"sgcca"`, `"rgcca"`, `"pca"`, `"spca"`, `"sipca`.
- `comp` integer value indicating the component of interest.
- `block` for an object of class `"sgcca"`, the block data sets can be specified as an input vector, for example `c(1,2)` for the first two blocks. Default to NULL (all block data sets)

**Details**

- `selectVar` provides the variables selected on a given component.
- `list("name")` outputs the name of the selected variables (provided that the input data have column names) ranked in decreasing order of importance.
- `list("value")` outputs the loading value for each selected variable, the loadings are ranked according to their absolute value.

These functions are only implemented for the sparse versions.
Value
none

**sipca**

*Independent Principal Component Analysis*

**Description**

Performs sparse independent principal component analysis on the given data matrix to enable variable selection.

**Usage**

```r
sipca(
    X,
    ncomp = 3,
    mode = c("deflation", "parallel"),
    fun = c("logcosh", "exp"),
    scale = FALSE,
    max.iter = 200,
    tol = 1e-04,
    keepX = rep(50, ncomp),
    w.init = NULL
)
```
Arguments

- **X**: a numeric matrix (or data frame).
- **ncomp**: integer, number of independent component to choose. Set by default to 3.
- **mode**: character string. What type of algorithm to use when estimating the unmixing matrix, choose one of "deflation", "parallel". Default set to deflation.
- **fun**: the function used in approximation to neg-entropy in the FastICA algorithm. Default set to logcosh, see details of FastICA.
- **scale**: (Default=FALSE) Logical indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.
- **max.iter**: integer, the maximum number of iterations.
- **tol**: a positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged, see fastICA package.
- **keepX**: the number of variable to keep on each dimensions.
- **w.init**: initial un-mixing matrix (unlike fastICA, this matrix is fixed here).

Details

See Details of ipca.

Soft thresholding is implemented on the independent loading vectors to obtain sparse loading vectors and enable variable selection.

Value

pca returns a list with class “ipca” containing the following components:

- **ncomp**: the number of principal components used.
- **unmixing**: the unmixing matrix of size (ncomp x ncomp)
- **mixing**: the mixing matrix of size (ncomp x ncomp
- **X**: the centered data matrix
- **x**: the principal components (with sparse independent loadings)
- **loadings**: the sparse independent loading vectors
- **kurtosis**: the kurtosis measure of the independent loading vectors
- **prop_expl_var**: Proportion of the explained variance of derived components, after setting possible missing values to zero.

Examples

data(liver.toxicity)

# implement IPCA on a microarray dataset
sipca.res <- sipca(liver.toxicity$gene, ncomp = 3, mode="deflation", keepX=c(50,50,50))
sipca.res

# samples representation
plotIndiv(sipca.res, ind.names = liver.toxicity$treatment[, 4],
  group = as.numeric(as.factor(liver.toxicity$treatment[, 4])))

## Not run:
plotIndiv(sipca.res, cex = 0.01,
  col = as.numeric(as.factor(liver.toxicity$treatment[, 4])),
  style="3d")

# variables representation
plotVar(sipca.res, cex = 2.5)

plotVar(sipca.res, rad.in = 0.5, cex = .6, style="3d")

## End(Not run)
Usage

```r
spca(
  X,
  ncomp = 2,
  center = TRUE,
  scale = TRUE,
  keepX = rep(ncol(X), ncomp),
  max.iter = 500,
  tol = 1e-06,
  logratio = c("none", "CLR"),
  multilevel = NULL,
  verbose.call = FALSE
)
```

Arguments

- **X**
  - a numeric matrix (or data frame) which provides the data for the sparse principal components analysis. It should not contain missing values.
- **ncomp**
  - Integer, if data is complete ncomp decides the number of components and associated eigenvalues to display from the pcasvd algorithm and if the data has missing values, ncomp gives the number of components to keep to perform the reconstitution of the data using the NIPALS algorithm. If NULL, function sets ncomp = min(nrow(X),ncol(X))
- **center**
  - (Default=TRUE) Logical, whether the variables should be shifted to be zero centered. Only set to FALSE if data have already been centered. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale. If the data contain missing values, columns should be centered for reliable results.
- **scale**
  - (Default=TRUE) Logical indicating whether the variables should be scaled to have unit variance before the analysis takes place.
- **keepX**
  - numeric vector of length ncomp, the number of variables to keep in loading vectors. By default all variables are kept in the model. See details.
- **max.iter**
  - Integer, the maximum number of iterations in the NIPALS algorithm.
- **tol**
  - Positive real, the tolerance used in the NIPALS algorithm.
- **logratio**
  - one of ('none','CLR'). Specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'
- **multilevel**
  - sample information for multilevel decomposition for repeated measurements.
- **verbose.call**
  - Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

scale= TRUE is highly recommended as it will help obtaining orthogonal sparse loading vectors.
keepX is the number of variables to select in each loading vector, i.e. the number of variables with non zero coefficient in each loading vector.

Note that data can contain missing values only when logratio = 'none' is used. In this case, center=TRUE should be used to center the data in order to effectively ignore the missing values. This is the default behaviour in spca.

According to Filzmoser et al., a ILR log ratio transformation is more appropriate for PCA with compositional data. Both CLR and ILR are valid.

Logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through logratio.transfo and withinVariation respectively.

Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset). For ILR transformation and additional offset might be needed.

The principal components are not guaranteed to be orthogonal in sPCA. We adopt the approach of Shen and Huang 2008 (Section 2.3) to estimate the explained variance in the case where the sparse loading vectors (and principal components) are not orthogonal. The data are projected onto the space spanned by the first loading vectors and the variance explained is then adjusted for potential correlation between PCs. Note that in practice, the loading vectors tend to be orthogonal if the data are centered and scaled in sPCA.

Value

spca returns a list with class "spca" containing the following components:

- **call** if verbose.call = FALSE, then just the function call is returned. If verbose.call = TRUE then all the inputted values are accessible via this component
- **ncomp** the number of components to keep in the calculation.
- **prop_expl_var** the adjusted percentage of variance explained for each component.
- **cum.var** the adjusted cumulative percentage of variances explained.
- **keepX** the number of variables kept in each loading vector.
- **iter** the number of iterations needed to reach convergence for each component.
- **rotation** the matrix containing the sparse loading vectors.
- **x** the matrix containing the principal components.

          legend = TRUE)
```

---

**spls**  
\textit{Sparse Partial Least Squares (sPLS)}

**Description**

Function to perform sparse Partial Least Squares (sPLS). The sPLS approach combines both integration and variable selection simultaneously on two data sets in a one-step strategy.

**Usage**

```r
spls(
  X, 
  Y, 
  ncomp = 2,
  mode = c("regression", "canonical", "invariant", "classic"),
  keepX, 
  keepY, 
  scale = TRUE, 
  tol = 1e-06,
)```
max.iter = 100,
near.zero.var = FALSE,
logratio = "none",
multilevel = NULL,
all.outputs = TRUE,
verbose.call = FALSE
)

Arguments

X numeric matrix of predictors with the rows as individual observations. missing values (NAs) are allowed.

Y numeric matrix of response(s) with the rows as individual observations matching X. missing values (NAs) are allowed.

ncomp Positive Integer. The number of components to include in the model. Default to 2.

mode Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

keepX numeric vector of length ncomp, the number of variables to keep in X-loadings. By default all variables are kept in the model.

keepY numeric vector of length ncomp, the number of variables

scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.

max.iter Integer, the maximum number of iterations. Default to 100.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.

logratio Character, one of ('none','CLR') specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'. See ?logratio.transfo for details.

multilevel Numeric, design matrix for repeated measurement analysis, where multilevel decomposition is required. For a one factor decomposition, the repeated measures on each individual, i.e. the individuals ID is input as the first column. For a 2 level factor decomposition then 2nd AND 3rd columns indicate those factors. See examples.

all.outputs Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

verbose.call Logical (Default=FALSE), if set to TRUE then the $call component of the returned object will contain the variable values for all parameters. Note that this may cause large memory usage.

Details

spls function fit sPLS models with 1,...,ncomp components. Multi-response models are fully supported. The X and Y datasets can contain missing values.
Value

`spls` returns an object of class "`spls`", a list that contains the following components:

- **call**: if `verbose.call = FALSE`, then just the function call is returned. If `verbose.call = TRUE` then all the inputted values are accessible via this component.
- **X**: the centered and standardized original predictor matrix.
- **Y**: the centered and standardized original response vector or matrix.
- **ncomp**: the number of components included in the model.
- **mode**: the algorithm used to fit the model.
- **keepX**: number of `X` variables kept in the model on each component.
- **keepY**: number of `Y` variables kept in the model on each component.
- **variates**: list containing the variates.
- **loadings**: list containing the estimated loadings for the `X` and `Y` variates.
- **names**: list containing the names to be used for individuals and variables.
- **tol**: the tolerance used in the iterative algorithm, used for subsequent S3 methods.
- **iter**: Number of iterations of the algorithm for each component.
- **max.iter**: the maximum number of iterations, used for subsequent S3 methods.
- **nzv**: list containing the zero- or near-zero predictors information.
- **scale**: whether scaling was applied per predictor.
- **logratio**: whether log ratio transformation for relative proportion data was applied, and if so, which type of transformation.
- **prop_expl_var**: Proportion of variance explained per component (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).
- **input.X**: numeric matrix of predictors in `X` that was input, before any saling / logratio / multilevel transformation.
- **mat.c**: matrix of coefficients from the regression of `X` / residual matrices `X` on the `X`-variates, to be used internally by `predict`.
- **defl.matrix**: residual matrices `X` for each dimension.

missing values

The estimation of the missing values can be performed using the `impute.nipals` function. Otherwise, missing values are handled by element-wise deletion in the `plS` function without having to delete the rows with missing data.

multilevel

Multilevel (s)PLS enables the integration of data measured on two different data sets on the same individuals. This approach differs from multilevel sPLS-DA as the aim is to select subsets of variables from both data sets that are highly positively or negatively correlated across samples. The approach is unsupervised, i.e. no prior knowledge about the sample groups is included.
**logratio and multilevel**

logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

**Examples**

```r
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic

toxicity.spls <- spls(X, Y, ncomp = 2, keepX = c(50, 50),
keepY = c(10, 10))
toxicity.spls <- spls(X, Y[,1:2,drop=FALSE], ncomp = 5, keepX = c(50, 50))# mode="canonical")```
## Second example: one-factor multilevel analysis with sPLS, selecting a subset of variables

```r
data(liver.toxicity)
# note: we made up those data, pretending they are repeated measurements
repeat.indiv <- c(1, 2, 1, 2, 1, 2, 1, 2, 3, 3, 4, 3, 4, 3, 4, 4, 5, 6, 5, 5,
6, 5, 6, 7, 7, 8, 6, 7, 8, 7, 8, 8, 9, 10, 9, 10, 11, 9, 9,
10, 11, 12, 12, 10, 11, 12, 11, 12, 13, 14, 13, 14, 13, 14,
13, 14, 15, 16, 15, 16, 15, 16, 15, 16)
summary(as.factor(repeat.indiv)) # 16 rats, 4 measurements each
# this is a spls (unsupervised analysis) so no need to mention any factor in design
# we only perform a one level variation split
design <- data.frame(sample = repeat.indiv)
res.spls.1level <- spls(X = liver.toxicity$gene,
Y=liver.toxicity$clinic,
multilevel = design,
ncomp = 3,
keepX = c(50, 50, 50), keepY = c(5, 5, 5),
mode = 'canonical')

# set up colors and pch for plotIndiv
col.stimu <- 1:nlevels(design$stimu)
plotIndiv(res.spls.1level, rep.space = 'X-variate', ind.names = FALSE,
group = liver.toxicity$treatment$Dose.Group,
pch = 20, main = 'Gene expression subspace',
legend = TRUE)
plotIndiv(res.spls.1level, rep.space = 'Y-variate', ind.names = FALSE,
group = liver.toxicity$treatment$Dose.Group,
pch = 20, main = 'Clinical measurements subspace',
legend = TRUE)
plotIndiv(res.spls.1level, rep.space = 'XY-variate', ind.names = FALSE,
group = liver.toxicity$treatment$Dose.Group,
pch = 20, main = 'Both Gene expression and Clinical subspaces',
legend = TRUE)
```

## Third example: two-factor multilevel analysis with sPLS, selecting a subset of variables

```r
data(liver.toxicity)
dose <- as.factor(liver.toxicity$treatment$Dose.Group)
time <- as.factor(liver.toxicity$treatment$Time.Group)
# note: we made up those data, pretending they are repeated measurements
repeat.indiv <- c(1, 2, 1, 2, 1, 2, 1, 2, 3, 3, 4, 3, 4, 3, 4, 4, 5, 6, 5, 5,
6, 5, 6, 7, 7, 8, 6, 7, 8, 7, 8, 8, 9, 10, 9, 10, 11, 9, 9,
10, 11, 12, 12, 10, 11, 12, 11, 12, 13, 14, 13, 14, 13, 14,
13, 14, 15, 16, 15, 16, 15, 16, 15, 16)
```
summary(as.factor(repeat.indiv)) # 16 rats, 4 measurements each
design <- data.frame(sample = repeat.indiv, dose = dose, time = time)

res.spls.2level = spls(liver.toxicity$gene,
Y = liver.toxicity$clinic,
multilevel = design,
ncomp=2,
keepX = c(10,10), keepY = c(5,5))
## End(Not run)

---

**splsda**

Sparse Partial Least Squares Discriminant Analysis (sPLS-DA)

**Description**

Function to perform sparse Partial Least Squares to classify samples (supervised analysis) and select variables.

**Usage**

splsda(
  X,
  Y,
  ncomp = 2,
  keepX,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  logratio = "none",
  multilevel = NULL,
  all.outputs = TRUE
)

**Arguments**

- **X**
  - numeric matrix of predictors with the rows as individual observations. missing values (NAs) are allowed.
- **Y**
  - a factor or a class vector for the discrete outcome.
- **ncomp**
  - Positive Integer. The number of components to include in the model. Default to 2.
- **keepX**
  - numeric vector of length ncomp, the number of variables to keep in $X$-loadings. By default all variables are kept in the model.
- **scale**
  - Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
tol  Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.
max.iter  Integer, the maximum number of iterations. Default to 100.
near.zero.var  Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.
logratio  Character, one of ('none','CLR') specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'. See ?logratio.transfo for details.
multilevel  sample information for multilevel decomposition for repeated measurements. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples in ?splsda.
all.outputs  Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details
splsda function fits an sPLS model with 1,...,ncomp components to the factor or class vector Y. The appropriate indicator (dummy) matrix is created.
Logratio transformation and multilevel analysis are performed sequentially as internal pre-processing step, through logratio.transfo and withinVariation respectively. Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset).
The type of deflation used is 'regression' for discriminant algorithms. i.e. no deflation is performed on Y.

Value
splsda returns an object of class "splsda", a list that contains the following components:

X  the centered and standardized original predictor matrix.
Y  the centered and standardized indicator response vector or matrix.
ind.mat  the indicator matrix.
ncomp  the number of components included in the model.
keepX  number of X variables kept in the model on each component.
variates  list containing the variates.
loadings  list containing the estimated loadings for the X and Y variates.
names  list containing the names to be used for individuals and variables.
nzv  list containing the zero- or near-zero predictors information.
tol  the tolerance used in the iterative algorithm, used for subsequent S3 methods
iter  Number of iterations of the algorithm for each component
max.iter  the maximum number of iterations, used for subsequent S3 methods
scale  Logical indicating whether the data were scaled in MINT S3 methods
logratio whether logratio transformations were used for compositional data
prop_expl_var Proportion of variance explained per component after setting possible missing values in the data to zero (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).
mat.c matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
defl.matrix residual matrices X for each dimension.

```
## First example
data(breast.tumors)
X <- breast.tumors$gene.exp
# Y will be transformed as a factor in the function,
# but we set it as a factor to set up the colors.
Y <- as.factor(breast.tumors$sample$treatment)
res <- splsda(X, Y, ncomp = 2, keepX = c(25, 25))

# individual names appear
plotIndiv(res, ind.names = Y, legend = TRUE, ellipse = TRUE)
```

```
## Not run:
## Second example: one-factor analysis with sPLS-DA, selecting a subset of variables
# as in the paper Liquet et al.
```
```r
#--------------------------------------------------------------
data(vac18)
X <- vac18$genes
Y <- vac18$stimulation
# sample indicates the repeated measurements
design <- data.frame(sample = vac18$sample)
Y = data.frame(stimul = vac18$stimulation)

# multilevel sPLS-DA model
res.1level <- splsda(X, Y = Y, ncomp = 3, multilevel = design,
keepX = c(30, 137, 123))

# set up colors for plotIndiv
col.stim <- c("darkblue", "purple", "green4","red3")
plotIndiv(res.1level, ind.names = Y, col.per.group = col.stim)

## Third example: two-factor analysis with sPLS-DA, selecting a subset of variables
# as in the paper Liquet et al.
#--------------------------------------------------------------
data(vac18.simulated) # simulated data
X <- vac18.simulated$genes
design <- data.frame(sample = vac18.simulated$sample)
Y = data.frame( stimu = vac18.simulated$stimulation,
time = vac18.simulated$time)
res.2level <- splsda(X, Y = Y, ncomp = 2, multilevel = design,
keepX = c(200, 200))
plotIndiv(res.2level, group = Y$stimu, ind.names = vac18.simulated$time,
legend = TRUE, style = 'lattice')

## Fourth example: with more than two classes
# ------------------------------------------------
data(liver.toxicity)
X <- as.matrix(liver.toxicity$gene)
# Y will be transformed as a factor in the function,
# but we set it as a factor to set up the colors.
Y <- as.factor(liver.toxicity$treatment[, 4])
splsda.liver <- splsda(X, Y, ncomp = 2, keepX = c(20, 20))

# individual name is set to the treatment
plotIndiv(splsda.liver, ind.names = Y, ellipse = TRUE, legend = TRUE)

## Fifth example: 16S data with multilevel decomoposition and log ratio transformation
# --------------------------------------------------------------
```
srbct.16S = splsda(
X = diverse.16S$data.TSS, # TSS normalised data
Y = diverse.16S$bodysite,
multilevel = diverse.16S$sample, # multilevel decomposition
ncomp = 2,
keepX = c(10, 150),
logratio= 'CLR') # CLR log ratio transformation

plotIndiv(splsda.16S, ind.names = FALSE, pch = 16, ellipse = TRUE, legend = TRUE)
#OTUs selected at the family level
diverse.16S$taxonomy[selectVar(splsda.16S, comp = 1)$name,'Family']

## End(Not run)

---

**srbct**

*Small version of the small round blue cell tumors of childhood data*

**Description**

This data set from Khan et al. (2001) gives the expression measure of 2308 genes measured on 63 samples.

**Usage**

data(srbct)

**Format**

A list containing the following components:

- **list("gene")** data frame with 63 rows and 2308 columns. The expression measure of 2308 genes for the 63 subjects.
- **list("class")** A class vector containing the class tumour of each case (4 classes in total).
- **list("gene.name")** data frame with 2308 rows and 2 columns containing further information on the genes.

**Value**

none

**Source**

**References**

Description

This data set contains the expression of a random subset of 400 genes in 125 samples from 4 independent studies and 3 cell types.

Usage

data(stemcells)

Format

A list containing the following components:

- list("gene") data matrix with 125 rows and 400 columns. Each row represents an experimental sample, and each column a single gene.
- list("celltype") a factor indicating the cell type of each sample.
- list("study") a factor indicating the study from which the sample was extracted.

Details

This data set contains the expression of a random subset of 400 genes in 125 samples from 4 independent studies and 3 cell types. Those studies can be combined and analysed using the MINT procedure.

Value

none

References

**study_split**

Divides a data matrix in a list of matrices defined by a factor

**Description**

`study_split` divides a data matrix in a list of matrices defined by a study input.

**Usage**

```r
study_split(data, study)
```

**Arguments**

- **data**: numeric matrix of predictors
- **study**: grouping factor indicating which samples are from the same study

**Value**

`study_split` simply returns a list of the same length as the number of levels of study that contains sub-matrices of `data`.

**Author(s)**

Florian Rohart, Al J Abadi

**See Also**

`mint.pls`, `mint.spls`, `mint.plsda`, `mint.splsda`.

**Examples**

```r
data(stemcells)
data = stemcells$gene
exp = stemcells$study

data.list = study_split(data, exp)

names(data.list)
lapply(data.list, dim)
table(exp)
```
Summary Methods for CCA and PLS objects

Description

Produce summary methods for class "rcc", "pls" and "spls".

Usage

## S3 method for class 'mixo_pls'
summary(
  object,
  what = c("all", "communalities", "redundancy", "VIP"),
  digits = 4,
  keep.var = FALSE,
  ...
)

## S3 method for class 'mixo_spls'
summary(
  object,
  what = c("all", "communalities", "redundancy", "VIP"),
  digits = 4,
  keep.var = FALSE,
  ...
)

## S3 method for class 'rcc'
summary(
  object,
  what = c("all", "communalities", "redundancy"),
  cutoff = NULL,
  digits = 4,
  ...
)

## S3 method for class 'pca'
summary(object, ...)

Arguments

object object of class inherited from "rcc", "pls" or "spls".
what character string or vector. Should be a subset of c("all", "summarised", "communalities", "redundancy", "VIP"). "VIP" is only available for (s)PLS. See Details.
digits integer, the number of significant digits to use when printing. Defaults to 4.
**summary**

keep.var Logical. If TRUE only the variables with loadings not zero (as selected by spls) are showed. Defaults to FALSE.

... not used currently.

cutoff real between 0 and 1. Variables with all correlations components below this cut-off in absolute value are not showed (see Details).

**Details**

The information in the rcc, pls or spls object is summarised, it includes: the dimensions of X and Y data, the number of variates considered, the canonical correlations (if object of class "rcc") and the (s)PLS algorithm used (if object of class "pls" or "spls") and the number of variables selected on each of the sPLS components (if x of class "spls").

"communalities" in what gives Communalities Analysis. "redundancy" display Redundancy Analysis. "VIP" gives the Variable Importance in the Projection (VIP) coefficients fit by pls or spls. If what is "all", all are given.

For class "rcc", when a value to cutoff is specified, the correlations between each variable and the equiangular vector between X- and Y-variates are computed. Variables with at least one correlation componente bigger than cutoff are showed. The defaults is cutoff=NULL all the variables are given.

**Value**

The function summary returns a list with components:

- **ncomp** the number of components in the model.
- **cor** the canonical correlations.
- **cutoff** the cutoff used.
- **keep.var** list containing the name of the variables selected.
- **mode** the algorithm used in pls or spls.
- **Cm** list containing the communalities.
- **Rd** list containing the redundancy.
- **VIP** matrix of VIP coefficients.
- **what** subset of c("all","communalities","redundancy","VIP").
- **digits** the number of significant digits to use when printing.
- **method** method used: rcc, pls or spls.

**Author(s)**

Sébastien Déjean, Ignacio González, Kim-Anh Lê Cao, Al J Abadi

**See Also**

rcc, pls, spls, vip.
Examples

```r
## summary for objects of class 'rcc'
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res <- rcc(X, Y, ncomp = 3, lambda1 = 0.064, lambda2 = 0.008)
more <- summary(nutri.res, cutoff = 0.65)

## Not run:
## summary for objects of class 'pls'
data(linnerud)
X <- linnerud$exercise
Y <- linnerud$physiological
linn.pls <- pls(X, Y)
more <- summary(linn.pls)

## summary for objects of class 'spls'
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic
toxicity.spls <- spls(X, Y, ncomp = 3, keepX = c(50, 50, 50),
keepY = c(10, 10, 10))
more <- summary(toxicity.spls, what = "redundancy", keep.var = TRUE)

## End(Not run)
```

---

**tune**

Wrapper function to tune pls-derived methods.

**Description**

This function uses repeated cross-validation to tune hyperparameters such as the number of features to select and possibly the number of components to extract.

**Usage**

```r
tune(
  method = c("spls", "splsda", "mint.splsda", "rcc", "pca", "spca"),
  X,
  Y,
  multilevel = NULL,
  ncomp,
  study,
  test.keepX = c(5, 10, 15),
  test.keepY = NULL,
  already.tested.X,
  already.tested.Y,
```
mode = c("regression", "canonical", "invariant", "classic"),
nrepeat = 1,
grid1 = seq(0.001, 1, length = 5),
grid2 = seq(0.001, 1, length = 5),
validation = "Mfold",
folds = 10,
dist = "max.dist",
measure = ifelse(method == "spls", "cor", "BER"),
auc = FALSE,
progressBar = FALSE,
near.zero.var = FALSE,
logratio = c("none", "CLR"),
center = TRUE,
scale = TRUE,
max.iter = 100,
tol = 1e-09,
light.output = TRUE,
BPPARAM = SerialParam()
)

Arguments

method
This parameter is used to pass all other argument to the suitable function. method
has to be one of the following: "spls", "splsda", "mint.splsda", "rcc", "pca",
"spca" or "pls".

X
numeric matrix of predictors. NAs are allowed.

Y
Either a factor or a class vector for the discrete outcome, or a numeric vector or
matrix of continuous responses (for multi-response models).

multilevel
Design matrix for multilevel analysis (for repeated measurements) that indicates
the repeated measures on each individual, i.e. the individuals ID. See Details.

ncomp
the number of components to include in the model.

study
grouping factor indicating which samples are from the same study

test.keepX
numeric vector for the different number of variables to test from the X data set

test.keepY
If method = 'spls', numeric vector for the different number of variables to test
from the Y data set

already.tested.X
Optional, if ncomp > 1 A numeric vector indicating the number of variables to
select from the X data set on the firsts components.

already.tested.Y
if method = 'spls' and if(ncomp > 1) numeric vector indicating the number
of variables to select from the Y data set on the first components

mode
character string. What type of algorithm to use, (partially) matching one of
"regression", "canonical", "invariant" or "classic". See Details.

nrepeat
Number of times the Cross-Validation process is repeated.
grid1, grid2 vector numeric defining the values of lambda1 and lambda2 at which cross-validation score should be computed. Defaults to grid1=grid2=seq(0.001, 1, length=5).

validation character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".

folds the folds in the Mfold cross-validation. See Details.

dist distance metric to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).

measure The tuning measure used for different methods. See details.

auc if TRUE calculate the Area Under the Curve (AUC) performance of the model.

progressBar by default set to TRUE to output the progress bar of the computation.

near.zero.var Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE

logratio one of ('none','CLR'). Default to 'none'

center a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.

scale a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.

max.iter Integer, the maximum number of iterations.

tol Numeric, convergence tolerance criteria.

light.output if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.

BPPARAM A BiocParallelParam object indicating the type of parallelisation. See examples.

Details

See the help file corresponding to the corresponding method, e.g. tune.splsda for further details. Note that only the arguments used in the tune function corresponding to method are passed on.

More details about the prediction distances in ?predict and the supplemental material of the mixOmics article (Rohart et al. 2017). More details about the PLS modes are in ?pls.

Value

Depending on the type of analysis performed and the input arguments, a list that may contain:

error.rate returns the prediction error for each test.keepX on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.

choice.keepX returns the number of variables selected (optimal keepX) on each component.
choice.ncomp

For supervised models; returns the optimal number of components for the model for each prediction distance using one-sided t-tests that test for a significant difference in the mean error rate (gain in prediction) when components are added to the model. See more details in Rohart et al 2017 Suppl. For more than one block, an optimal ncomp is returned for each prediction framework.

error.rate.class

returns the error rate for each level of \( Y \) and for each component computed with the optimal keepX

predict

Prediction values for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

class

Predicted class for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

auc

AUC mean and standard deviation if the number of categories in \( Y \) is greater than 2, see details above. Only if auc = TRUE

cor.value

only if multilevel analysis with 2 factors: correlation between latent variables.

tune.block.splsda  Tuning function for block.splsda method (N-integration with sparse Discriminant Analysis)

Description

Computes M-fold or Leave-One-Out Cross-Validation scores based on a user-input grid to determine the optimal parsity parameters values for method block.splsda.
tune.block.splsda

Usage

tune.block.splsda(
  X,
  Y,
  indY,
  ncomp = 2,
  test.keepX,
  already.tested.X,
  validation = "Mfold",
  folds = 10,
  dist = "max.dist",
  measure = "BER",
  weighted = TRUE,
  progressBar = FALSE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  nrepeat = 1,
  design,
  scheme = "horst",
  scale = TRUE,
  init = "svd",
  light.output = TRUE,
  signif.threshold = 0.01,
  BPPARAM = SerialParam(),
  ...
)

Arguments

X | A named list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.

Y | a factor or a class vector for the discrete outcome.

indY | To supply if Y is missing, indicates the position of the matrix response in the list X.

ncomp | the number of components to include in the model. Default to 2. Applies to all blocks.

test.keepX | A named list with the same length and names as X (without the outcome Y, if it is provided in X and designated using indY). Each entry of this list is a numeric vector for the different keepX values to test for that specific block.

already.tested.X | Optional, if ncomp > 1 A named list of numeric vectors each of length n_tested indicating the number of variables to select from the X data set on the first n_tested components.

validation | character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
folds the folds in the Mfold cross-validation. See Details.
dist distance metric to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).
measure The tuning measure used for different methods. See details.
weighted tune using either the performance of the Majority vote or the Weighted vote.
progressBar by default set to TRUE to output the progress bar of the computation.
tol Positive numeric used as convergence criteria/tolerance during the iterative process. Default to 1e-06.
max.iter Integer, the maximum number of iterations. Default to 100.
near.zero.var Logical, see the internal nearZeroVar function (should be set to FALSE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE.
nrepeat Number of times the Cross-Validation process is repeated.
design numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. Alternatively, one of c(‘null’, ‘full’) indicating a disconnected or fully connected design, respectively, or a numeric between 0 and 1 which will designate all off-diagonal elements of a fully connected design (see examples in block.splsda). If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme Either "horst", "factorial" or "centroid". Default = centroid, see reference.
scale Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
init Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y (’svd’) or each block independently (’svd.single’). Default = svd.single
light.output if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.
signif.threshold numeric between 0 and 1 indicating the significance threshold required for improvement in error rate of the components. Default to 0.01.
BPPARAM A BiocParallelParam object indicating the type of parallelisation. See examples.

Details

This tuning function should be used to tune the keepX parameters in the block.splsda function (N-integration with sparse Discriminant Analysis).
M-fold or LOO cross-validation is performed with stratified subsampling where all classes are represented in each fold.

If validation = "Mfold", M-fold cross-validation is performed. The number of folds to generate is to be specified in the argument folds.

If validation = "loo", leave-one-out cross-validation is performed. By default folds is set to the number of unique individuals.

All combination of test.keepX values are tested. A message informs how many will be fitted on each component for a given test.keepX.

More details about the prediction distances in predict and the supplemental material of the mixOmics article (Rohart et al. 2017). Details about the PLS modes are in ?pls.

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

Value

A list that contains:

- error.rate: returns the prediction error for each test.keepX on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.

- choice.keepX: returns the number of variables selected (optimal keepX) on each component, for each block.

- choice.ncomp: returns the optimal number of components for the model fitted with $choice.keepX.

- error.rate.class: returns the error rate for each level of Y and for each component computed with the optimal keepX.

- predict: Prediction values for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

- class: Predicted class for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

- cor.value: compute the correlation between latent variables for two-factor sPLS-DA analysis.

tune.mint.splsda  
Estimate the parameters of mint.splsda method

Description

Computes Leave-One-Group-Out-Cross-Validation (LOGOCV) scores on a user-input grid to determine optimal values for the sparsity parameters in mint.splsda.

Usage

tune.mint.splsda(
  X,
  Y,
  ncomp = 1,
  study,
  test.keepX = c(5, 10, 15),
  already.tested.X,
  dist = c("max.dist", "centroids.dist", "mahalanobis.dist"),
  measure = c("BER", "overall"),
  auc = FALSE,
  progressBar = FALSE,
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  light.output = TRUE,
  signif.threshold = 0.01
)

Arguments

X numeric matrix of predictors. NAs are allowed.
Y Outcome. Numeric vector or matrix of responses (for multi-response models)
ncomp Number of components to include in the model (see Details). Default to 1
study grouping factor indicating which samples are from the same study
test.keepX numeric vector for the different number of variables to test from the X data set
already.tested.X

if ncomp > 1 Numeric vector indicating the number of variables to select from the X data set on the firsts components

dist

only applies to an object inheriting from "plsda" or "splsda" to evaluate the classification performance of the model. Should be a subset of "max.dist", "centroids.dist", "mahalanobis.dist". Default is "all". See predict.

measure

Two misclassification measure are available: overall misclassification error overall or the Balanced Error Rate BER

auc

if TRUE calculate the Area Under the Curve (AUC) performance of the model.

progressBar

by default set to TRUE to output the progress bar of the computation.

scale

Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

tol

Convergence stopping value.

max.iter

integer, the maximum number of iterations.

near.zero.var

Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE

light.output

if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.

signif.threshold

numeric between 0 and 1 indicating the significance threshold required for improvement in error rate of the components. Default to 0.01.

Details

This function performs a Leave-One-Group-Out-Cross-Validation (LOGOCV), where each of study is left out once. It returns a list of variables of X that were selected on each of the ncomp components. Then, a mint.plsda can be performed with keepX set as the output choice.keepX.

All component 1 : ncomp are tuned, except the first ones for which a already.tested.X is provided. See examples below.

The function outputs the optimal number of components that achieve the best performance based on the overall error rate or BER. The assessment is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when adding a component to the model. Our experience has shown that in most case, the optimal number of components is the number of categories in Y - 1, but it is worth tuning a few extra components to check (see our website and case studies for more details).

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

More details about the prediction distances in ?predict and the supplemental material of the mixOmics article (Rohart et al. 2017).

Value

The returned value is a list with components:
error.rate returns the prediction error for each test.keepX on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.

choice.keepX returns the number of variables selected (optimal keepX) on each component.

choice.ncomp returns the optimal number of components for the model fitted with $choice.keepX

error.rate.class returns the error rate for each level of Y and for each component computed with the optimal keepX

predict Prediction values for each sample, each test.keepX and each comp.

class Predicted class for each sample, each test.keepX and each comp.

# only tune component 2 and keeping 10 genes on comp1
tune.pca

Tune the number of principal components in PCA

Description
tune.pca can be used to quickly visualise the proportion of explained variance for a large number of principal components in PCA.

Usage
tune.pca(
  X,
  ncomp = NULL,
  center = TRUE,
  scale = FALSE,
  max.iter = 500,
  tol = 1e-09,
  logratio = c("none", "CLR", "ILR"),
  V = NULL,
  multilevel = NULL
)

Arguments

  X       numeric matrix of predictors. NAs are allowed.
  ncomp   integer, the number of components to initially analyse in tune.pca to choose a final ncomp for pca. If NULL, function sets ncomp = min(nrow(X), ncol(X))
  center  a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.
  scale   a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale.
  max.iter Integer, the maximum number of iterations.
  tol     Numeric, convergence tolerance criteria.
  logratio one of ('none', 'CLR', 'ILR'). Default to 'none'
  V       Matrix used in the logratio transformation id provided.
  multilevel Design matrix for multilevel analysis (for repeated measurements).
Details

The calculation is done either by a singular value decomposition of the (possibly centered and scaled) data matrix, if the data is complete or by using the NIPALS algorithm if there is data missing. Unlike `princomp`, the print method for these objects prints the results in a nice format and the `plot` method produces a bar plot of the percentage of variance explained by the principal components (PCs).

When using NIPALS (missing values), we make the assumption that the first \( \min(ncol(X), nrow(X)) \) principal components will account for 100 % of the explained variance.

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

Components are omitted if their standard deviations are less than or equal to `comp.tol` times the standard deviation of the first component. With the default null setting, no components are omitted. Other settings for `comp.tol` could be `comp.tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components, or `comp.tol = 0`.

Logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

Value

tune.pca returns a list with class "tune.pca" containing the following components:

- `sdev` the square root of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix.
- `prop_expl_var` The proportion of explained variance accounted for by each principal component.
- `cum.var` the cumulative proportion of explained variance accounted for by the sequential accumulation of principal components is calculated using the sum of the proportion of explained variance

data(liver.toxicity)
tune <- tune.pca(liver.toxicity$gene, center = TRUE, scale = TRUE)
tune
plot(tune)
**tune.rcc**

*Estimate the parameters of regularization for Regularized CCA*

**Description**

Computes leave-one-out or M-fold cross-validation scores on a two-dimensional grid to determine optimal values for the parameters of regularization in rcc.

**Usage**

```r
tune.rcc(
  X,
  Y,
  grid1 = seq(0.001, 1, length = 5),
  grid2 = seq(0.001, 1, length = 5),
  validation = c("loo", "Mfold"),
  folds = 10,
  plot = TRUE
)
```

**Arguments**

- **X** numeric matrix or data frame \((n \times p)\), the observations on the \(X\) variables. NAs are allowed.
- **Y** numeric matrix or data frame \((n \times q)\), the observations on the \(Y\) variables. NAs are allowed.
- **grid1, grid2** vector numeric defining the values of \(\lambda_1\) and \(\lambda_2\) at which cross-validation score should be computed. Defaults to \(\text{grid1}=\text{grid2} = \text{seq}(0.001, 1, \text{length}=5)\).
- **validation** character string. What kind of (internal) cross-validation method to use, (partially) matching one of "loo" (leave-one-out) or "Mfolds" (M-folds). See Details.
- **folds** positive integer. Number of folds to use if \(\text{validation}="\text{Mfold}"\). Defaults to \(\text{folds}=10\).
- **plot** logical argument indicating whether a image map should be plotted by calling the \text{imgCV} function.

**Details**

If \(\text{validation}="\text{Mfolds}"\), M-fold cross-validation is performed by calling \text{Mfold}. When \(\text{folds}\) is given, the elements of \(\text{folds}\) should be integer vectors specifying the indices of the validation sample and the argument \(M\) is ignored. Otherwise, the folds are generated. The number of cross-validation folds is specified with the argument \(M\).

If \(\text{validation}="\text{loo}"\), leave-one-out cross-validation is performed by calling the \text{loo} function. In this case the arguments \(\text{folds}\) and \(M\) are ignored.
The estimation of the missing values can be performed by the reconstitution of the data matrix using the \texttt{nipals} function. Otherwise, missing values are handled by casewise deletion in the \texttt{rcc} function.

**Value**

The returned value is a list with components:

- \texttt{opt.lambda1}  
  value of the parameters of regularization on which the cross-validation method reached it optimal.
- \texttt{opt.lambda2}  
- \texttt{opt.score}  
  the optimal cross-validation score reached on the grid.
- \texttt{grid1, grid2}  
  original vectors \texttt{grid1} and \texttt{grid2}.
- \texttt{mat}  
  matrix containing the cross-validation score computed on the grid.

**Examples**

```r
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene

## this can take some seconds

tune.rcc(X, Y, validation = "Mfold")
```

---

**tune.spca**  
*Tune number of selected variables for spca*

**Description**

This function performs sparse pca and optimises the number of variables to keep on each component using repeated cross-validation.
Usage

```r
tune.spca(
  X,
  ncomp = 2,
  nrepeat = 1,
  folds,
  test.keepX,
  center = TRUE,
  scale = TRUE,
  BPPARAM = SerialParam()
)
```

Arguments

- **X**: a numeric matrix (or data frame) which provides the data for the sparse principal components analysis. It should not contain missing values.

- **ncomp**: Integer, if data is complete, `ncomp` decides the number of components and associated eigenvalues to display from the `pcasvd` algorithm and if the data has missing values, `ncomp` gives the number of components to keep to perform the reconstitution of the data using the NIPALS algorithm. If `NULL`, function sets `ncomp = min(nrow(X), ncol(X))`.

- **nrepeat**: Number of times the Cross-Validation process is repeated.

- **folds**: Number of folds in 'Mfold' cross-validation. See details.

- **test.keepX**: numeric vector for the different number of variables to test from the `X` data set.

- **center**: (Default=TRUE) Logical, whether the variables should be shifted to be zero centered. Only set to FALSE if data have already been centered. Alternatively, a vector of length equal the number of columns of `X` can be supplied. The value is passed to `scale`. If the data contain missing values, columns should be centered for reliable results.

- **scale**: (Default=TRUE) Logical indicating whether the variables should be scaled to have unit variance before the analysis takes place.

- **BPPARAM**: A `BiocParallelParam` object indicating the type of parallelisation. See examples.

Details

Essentially, for the first component, and for a grid of the number of variables to select (`keepX`), a number of repeats and folds, data are split to train and test and the extracted components are compared against those from a `spca` model with all the data to ascertain the optimal `keepX`. In order to keep at least 3 samples in each test set for reliable scaling of the test data for comparison, `folds` must be `<= floor(nrow(X)/3)`.

The number of selected variables for the following components will then be sequentially optimised. If the number of observations are small (e.g. < 30), it is recommended to use Leave-One-Out Cross-Validation which can be achieved by setting `folds = nrow(X)`. 

Value

A `tune.spca` object containing:

- **call** The function call
- **choice.keepX** The selected number of components on each component
- **cor.comp** The correlations between the components from the cross-validated studies and those from the study which used all of the data in training.

Examples

data("nutrimouse")
set.seed(42)
nrepeat <- 5
tune.spca.res <- tune.spca(
  X = nutrimouse$lipid,
  ncomp = 2,
  nrepeat = nrepeat,
  folds = 3,
  test.keepX = seq(5, 15, 5)
)
tune.spca.res
plot(tune.spca.res)
## Not run:
## parallel processing using BiocParallel on repeats with more workers (cpus)
## You can use BiocParallel::MulticoreParam() on non_Windows machines
## for faster computation
BPPARAM <- BiocParallel::SnowParam(workers = max(parallel::detectCores()-1, 2))
tune.spca.res <- tune.spca(
  X = nutrimouse$lipid,
  ncomp = 2,
  nrepeat = nrepeat,
  folds = 3,
  test.keepX = seq(5, 15, 5),
  BPPARAM = BPPARAM
)
plot(tune.spca.res)
## End(Not run)
Usage

tune.spls(
  X,
  Y,
  test.keepX = NULL,
  test.keepY = NULL,
  ncomp,
  validation = c("Mfold", "loo"),
  nrepeat = 1,
  folds,
  mode = c("regression", "canonical", "classic"),
  measure = NULL,
  BPPARAM = SerialParam(),
  progressBar = FALSE,
  limQ2 = 0.0975,
  ...
)

Arguments

X numeric matrix of predictors with the rows as individual observations. missing values (NAs) are allowed.

Y numeric matrix of response(s) with the rows as individual observations matching X. missing values (NAs) are allowed.

test.keepX numeric vector for the different number of variables to test from the X data set.

test.keepY numeric vector for the different number of variables to test from the Y data set. Default to ncol(Y).

ncomp Positive Integer. The number of components to include in the model. Default to 2.

validation character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (Leave-One-out). Default is "Mfold".

nrepeat Positive integer. Number of times the Cross-Validation process should be repeated. nrepeat > 2 is required for robust tuning. See details.

folds Positive Integer. The folds in the Mfold cross-validation.

mode Character string indicating the type of PLS algorithm to use. One of "regression", "canonical", "invariant" or "classic". See Details.

measure The tuning measure to use. See details.

BPPARAM A BiocParallelParam object indicating the type of parallelisation. See examples in ?tune.spca.

progressBar Logical. If TRUE a progress bar is shown as the computation completes. Default to FALSE.

limQ2 Q2 threshold for recommending optimal ncomp.

... Optional parameters passed to spls
Value

A list that contains:

- `cor.pred` The correlation of predicted vs actual components from X (t) and Y (u) for each component.
- `RSS.pred` The Residual Sum of Squares of predicted vs actual components from X (t) and Y (u) for each component.
- `choice.keepX` returns the number of variables selected for X (optimal keepX) on each component.
- `choice.keepY` returns the number of variables selected for Y (optimal keepY) on each component.
- `choice.ncomp` returns the optimal number of components for the model fitted with `choice.keepX` and `choice.keepY`.
- `call` The functional call including the parameters used.

folds

During a cross-validation (CV), data are randomly split into M subgroups (folds). M-1 subgroups are then used to train submodels which would be used to predict prediction accuracy statistics for the held-out (test) data. All subgroups are used as the test data exactly once. If `validation = "loo"`, leave-one-out CV is used where each group consists of exactly one sample and hence M == N where N is the number of samples.

nrepeat

The cross-validation process is repeated nrepeat times and the accuracy measures are averaged across repeats. If `validation = "loo"`, the process does not need to be repeated as there is only one way to split N samples into N groups and hence nrepeat is forced to be 1.

measure

- **For PLS2** Two measures of accuracy are available: Correlation (`cor`, used as default), as well as the Residual Sum of Squares (`RSS`). For `cor`, the parameters which would maximise the correlation between the predicted and the actual components are chosen. The `RSS` measure tries to predict the held-out data by matrix reconstruction and seeks to minimise the error between actual and predicted values. For `mode = 'canonical'`, the X matrix is used to calculate the `RSS`, while for others modes the Y matrix is used. This measure gives more weight to any large errors and is thus sensitive to outliers. It also intrinsically selects less number of features on the Y block compared to `measure = 'cor'`.

- **For PLS1** Four measures of accuracy are available: Mean Absolute Error (`MAE`), Mean Square Error (`MSE`, used as default), Bias and R2. Both `MAE` and `MSE` average the model prediction error. `MAE` measures the average magnitude of the errors without considering their direction. It is the average over the fold test samples of the absolute differences between the Y predictions and the actual Y observations. The `MSE` also measures the average magnitude of the error. Since the errors are squared before they are averaged, the `MSE` tends to give a relatively high weight to large errors. The Bias is the average of the differences between the Y predictions and the actual Y observations and the R2 is the correlation between the predictions and the observations.
Optimisation Process

The optimisation process is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when incrementing the number of features or components in the model. However, it will assess all the provided grid through pairwise comparisons as the performance criteria do not always change linearly with respect to the added number of features or components.

### Description

Computes M-fold or Leave-One-Out Cross-Validation scores on a user-input grid to determine optimal values for the sparsity parameters in `splsda`.

### Usage

```r
tune.splsda(
  X,
  Y,
  ncomp = 1,
  test.keepX = c(5, 10, 15),
  already.tested.X,
  validation = "Mfold",
  folds = 10,
  dist = "max.dist",
  measure = "BER",
  scale = TRUE,
  auc = FALSE,
  progressBar = FALSE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  nrepeat = 1,
  logratio = c("none", "CLR"),
  multilevel = NULL,
  light.output = TRUE,
  signif.threshold = 0.01,
  cpus = 1
)
```
Arguments

- **X**: numeric matrix of predictors. NAs are allowed.
- **Y**: if (method = 'spls') numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
- **ncomp**: the number of components to include in the model.
- **test.keepX**: numeric vector for the different number of variables to test from the X data set already.tested.X. Optional, if ncomp > 1 A numeric vector indicating the number of variables to select from the X data set on the first components.
- **validation**: character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (short for 'leave-one-out'). Default is "Mfold".
- **folds**: the folds in the Mfold cross-validation. See Details.
- **dist**: distance metric to use for splsda to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).
- **measure**: Three misclassification measure are available: overall misclassification error overall, the Balanced Error Rate BER or the Area Under the Curve AUC
- **scale**: Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
- **auc**: if TRUE calculate the Area Under the Curve (AUC) performance of the model based on the optimisation measure measure.
- **progressBar**: by default set to TRUE to output the progress bar of the computation.
- **tol**: Convergence stopping value.
- **max.iter**: integer, the maximum number of iterations.
- **near.zero.var**: Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE
- **nrepeat**: Number of times the Cross-Validation process is repeated.
- **logratio**: one of ('none','CLR'). Default to 'none'
- **multilevel**: Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
- **light.output**: if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.
- **signif.threshold**: numeric between 0 and 1 indicating the significance threshold required for improvement in error rate of the components. Default to 0.01.
- **cpus**: Number of cpus to use when running the code in parallel.

Details

This tuning function should be used to tune the parameters in the splsda function (number of components and number of variables in keepX to select).
For a sPLS-DA, M-fold or LOO cross-validation is performed with stratified subsampling where all classes are represented in each fold.

If validation = "loo", leave-one-out cross-validation is performed. By default folds is set to the number of unique individuals.

The function outputs the optimal number of components that achieve the best performance based on the overall error rate or BER. The assessment is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when adding a component to the model. Our experience has shown that in most case, the optimal number of components is the number of categories in Y - 1, but it is worth tuning a few extra components to check (see our website and case studies for more details).

For sPLS-DA multilevel one-factor analysis, M-fold or LOO cross-validation is performed where all repeated measurements of one sample are in the same fold. Note that logratio transform and the multilevel analysis are performed internally and independently on the training and test set.

For a sPLS-DA multilevel two-factor analysis, the correlation between components from the within-subject variation of X and the cond matrix is computed on the whole data set. The reason why we cannot obtain a cross-validation error rate as for the spls-DA one-factor analysis is because of the difficulty to decompose and predict the within matrices within each fold.

For a sPLS two-factor analysis a sPLS canonical mode is run, and the correlation between components from the within-subject variation of X and Y is computed on the whole data set.

If validation = "Mfold", M-fold cross-validation is performed. How many folds to generate is selected by specifying the number of folds in folds.

If auc = TRUE and there are more than 2 categories in Y, the Area Under the Curve is averaged using one-vs-all comparison. Note however that the AUC criteria may not be particularly insightful as the prediction threshold we use in sPLS-DA differs from an AUC threshold (sPLS-DA relies on prediction distances for predictions, see ?predict.splsda for more details) and the supplemental material of the mixOmics article (Rohart et al. 2017). If you want the AUC criterion to be insightful, you should use measure==AUC as this will output the number of variable that maximises the AUC; in this case there is no prediction threshold from sPLS-DA (dist is not used). If measure==AUC, we do not output SD as this measure can be a mean (over nrepeat) of means (over the categories).

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

More details about the prediction distances in ?predict and the supplemental material of the mixOmics article (Rohart et al. 2017).

**Value**

Depending on the type of analysis performed, a list that contains:

- **error.rate** returns the prediction error for each test.keepX on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.

- **choice.keepX** returns the number of variables selected (optimal keepX) on each component.

- **choice.ncomp** returns the optimal number of components for the model fitted with $choice.keepX
error.rate.class
returns the error rate for each level of Y and for each component computed with the optimal keepX.

predict
Prediction values for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

class
Predicted class for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE

auc
AUC mean and standard deviation if the number of categories in Y is greater than 2, see details above. Only if auc = TRUE

cor.value
only if multilevel analysis with 2 factors: correlation between latent variables.

Examples
## First example: analysis with sPLS-DA

data(breast.tumors)
X = breast.tumors$gene.exp
Y = as.factor(breast.tumors$sample$treatment)
tune = tune.splsda(X, Y, ncomp = 1, nrepeat = 10, logratio = "none",
test.keepX = c(5, 10, 15), folds = 10, dist = "max.dist",
progressBar = TRUE)

## Not run:
# 5 components, optimising 'keepX' and 'ncomp'
tune = tune.splsda(X, Y, ncomp = 5, test.keepX = c(5, 10, 15),
folds = 10, dist = "max.dist", nrepeat = 5, progressBar = FALSE)

tune$choice.ncomp
tune$choice.keepX
plot(tune)

## only tune component 3 and 4
# keeping 5 and 10 variables on the first two components respectively
tune = tune.splsda(X = X, Y = Y, ncomp = 4,
already.tested.X = c(5, 10),

## Second example: multilevel one-factor analysis with sPLS-DA

data(vac18)
X = vac18$genes
Y = vac18$stimulation
# sample indicates the repeated measurements
design = data.frame(sample = vac18$sample)

tune = tune.splsda(X, Y = Y, ncomp = 3, nrepeat = 10, logratio = "none",
test.keepX = c(5,50,100), folds = 10, dist = "max.dist", multilevel = design)

## End(Not run)

### Description

For a multilevel spls analysis, the tuning criterion is based on the maximisation of the correlation between the components from both data sets

### Usage

```r
tune.splslevel(
  X,
  Y,
  multilevel,
  ncomp = NULL,
  mode = "regression",
  test.keepX = rep(ncol(X), ncomp),
  test.keepY = rep(ncol(Y), ncomp),
  already.tested.X = NULL,
  already.tested.Y = NULL
)
```

### Arguments

- **X**: numeric matrix of predictors. NAs are allowed.
- **Y**: if(method = 'spls') numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
- **multilevel**: Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
- **ncomp**: the number of components to include in the model.
- **mode**: character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic".
tune.splslevel

test.keepX numeric vector for the different number of variables to test from the \(X\) data set
test.keepY numeric vector for the different number of variables to test from the \(Y\) data set
already.tested.X Optional, if \(ncomp > 1\) a numeric vector indicating the number of variables to select from the \(X\) data set on the firsts components.
already.tested.Y Optional, if \(ncomp > 1\) a numeric vector indicating the number of variables to select from the \(Y\) data set on the firsts components.

Details
For a multilevel spls analysis, the tuning criterion is based on the maximisation of the correlation between the components from both data sets.

Value

\(\text{cor.value}\) correlation between latent variables

repeat.indiv <- c(1, 2, 1, 2, 1, 2, 1, 2, 3, 3, 4, 4, 3, 4, 3, 4, 4, 5, 6, 5, 5,
6, 5, 6, 7, 7, 8, 6, 7, 8, 7, 8, 9, 9, 10, 10, 10, 11, 11, 11, 12, 12, 13, 14, 13, 14, 14,
13, 14, 15, 16, 15, 16, 15, 16, 16, 16, 16, 16, 16, 16, 16, 16)
summary(as.factor(repeat.indiv)) # 16 rats, 4 measurements each

# this is a spls (unsupervised analysis) so no need to mention any factor in design
# we only perform a one level variation split
design <- data.frame(sample = repeat.indiv)

tune.splslevel(X = liver.toxicity$gene,
Y=liver.toxicity$clinic,
multilevel = design,
test.keepX = c(5, 10, 15),
test.keepY = c(1, 2, 5),
ncomp = 1)
unmap

**Dummy matrix for an outcome factor**

**Description**

Converts a class or group vector or factor into a matrix of indicator variables.

**Usage**

```
unmap(classification, groups = NULL, noise = NULL)
```

**Arguments**

- `classification`: A numeric or character vector or factor. Typically the distinct entries of this vector would represent a classification of observations in a data set.
- `groups`: A numeric or character vector indicating the groups from which `classification` is drawn. If not supplied, the default is to assumed to be the unique entries of `classification`.
- `noise`: A single numeric or character value used to indicate the value of `groups` corresponding to noise.

**Value**

An $n$ by $K$ matrix of $(0,1)$ indicator variables, where $n$ is the length of samples and $K$ the number of classes in the outcome.

If a `noise` value of symbol is designated, the corresponding indicator variables are relocated to the last column of the matrix.

**Note:** - you can remap an unmap vector using the function `map` from the package mclust. - this function should be used to unmap an outcome vector as in the non-supervised methods of mixOmics. For other supervised analyses such as (s)PLS-DA, (s)gccaDA this function is used internally.

**Author(s)**

Ignacio Gonzalez, Kim-Anh Le Cao, Pierre Monget, AL J Abadi

**References**

Examples

data(nutrimouse)
Y = unmap(nutrimouse$diet)
Y
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid, Y = Y)
# data could then used as an input in wrapper.rgcca, which is not, technically, 
# a supervised method, see ??wrapper.rgcca

Description

The data come from a trial evaluating a vaccine based on HIV-1 lipopeptides in HIV-negative volunteers. The vaccine (HIV-1 LIPO-5 ANRS vaccine) contains five HIV-1 amino acid sequences coding for Gag, Pol and Nef proteins. This data set contains the expression measure of a subset of 1000 genes from purified in vitro stimulated Peripheral Blood Mononuclear Cells from 42 repeated samples (12 unique vaccinated participants) 14 weeks after vaccination, 6 hours after in vitro stimulation by either (1) all the peptides included in the vaccine (LIPO-5), or (2) the Gag peptides included in the vaccine (GAG+) or (3) the Gag peptides not included in the vaccine (GAG-) or (4) without any stimulation (NS).

Usage

data(vac18)

Format

A list containing the following components:

list("gene") data frame with 42 rows and 1000 columns. The expression measure of 1000 genes for the 42 samples (PBMC cells from 12 unique subjects).

list("stimulation") is a factor of 42 elements indicating the type of in vitro simulation for each sample.

list("sample") is a vector of 42 elements indicating the unique subjects (for example the value '1' correspond to the first patient PBMC cells). Note that the design of this study is unbalanced.

list("tab.prob.gene") is a data frame with 1000 rows and 2 columns, indicating the Illumina probe ID and the gene name of the annotated genes.

Details

This is a subset of the original study for illustrative purposes.

Value

none

Simulated data based on the vac18 study for multilevel analysis

Description
Simulated data based on the vac18 study to illustrate the use of the multilevel analysis for one and two-factor analysis with sPLS-DA. This data set contains the expression simulated of 500 genes.

Usage
data(vac18.simulated)

Format
A list containing the following components:

- list("genes") data frame with 48 rows and 500 columns. The simulated expression of 500 genes for 48 subjects.
- list("sample") a vector indicating the repeated measurements on each unique subject. See Details.
- list("stimulation") a factor indicating the stimulation condition on each sample.
- list("time") a factor indicating the time condition on each sample.

Details
In this cross-over design, repeated measurements are performed 12 experiments units (or unique subjects) for each of the 4 stimulations.

The simulation study was based on a mixed effects model (see reference for details). Ten clusters of 100 genes were generated. Amongst those, 4 clusters of genes discriminate the 4 stimulations (denoted LIPO5, GAG+, GAG- and NS) as follows: \\
\- 2 gene clusters discriminate (LIPO5, GAG+) versus (GAG-, NS) \\
\- 2 gene clusters discriminate LIPO5 versus GAG+, while GAG+ and NS have the same effect \\
\- 2 gene clusters discriminate GAG- versus NS, while LIPO5 and GAG+ have the same effect \\
\- the 4 remaining clusters represent noisy signal (no stimulation effect) \\

Only a subset of those genes are presented here (to save memory space).

Value
none

**vip**  
*Variable Importance in the Projection (VIP)*

**Description**

The function `vip` computes the influence on the \(Y\)-responses of every predictor \(X\) in the model.

**Usage**

`vip(object)`

**Arguments**

- **object**: object of class inheriting from "pls", "plsda", "spls" or "splsda".

**Details**

Variable importance in projection (VIP) coefficients reflect the relative importance of each \(X\) variable for each \(X\) variate in the prediction model. VIP coefficients thus represent the importance of each \(X\) variable in fitting both the \(X\)- and \(Y\)-variates, since the \(Y\)-variates are predicted from the \(X\)-variates.

VIP allows to classify the \(X\)-variables according to their explanatory power of \(Y\). Predictors with large VIP, larger than 1, are the most relevant for explaining \(Y\).

**Value**

`vip` produces a matrix of VIP coefficients for each \(X\) variable (rows) on each variate component (columns).

**Author(s)**

Sébastien Déjean, Ignacio Gonzalez, Florian Rohart, Al J Abadi

**References**

`pls`, `spls`, `summary`. 
withinVariation

Examples

```r
data(linnerud)
X <- linnerud$exercise
Y <- linnerud$physiological
linn.pls <- pls(X, Y)
linn.vip <- vip(linn.pls)

barplot(linn.vip,
beside = TRUE, col = c("lightblue", "mistyrose", "lightcyan"),
ylim = c(0, 1.7), legend = rownames(linn.vip),
main = "Variable Importance in the Projection", font.main = 4)
```

Description

This function is internally called by `pca`, `pls`, `spls`, `plsda` and `splsda` functions for cross-over design data, but can be called independently prior to any kind of multivariate analyses.

Usage

```r
withinVariation(X, design)
```

Arguments

- `X` numeric matrix of predictors. NAs are allowed.
- `design` a numeric matrix or data frame. The first column indicates the repeated measures on each individual, i.e. the individuals ID. The 2nd and 3rd columns are to split the variation for a 2 level factor.

Details

withinVariation function decomposes the Within variation in the X data set. The resulting $X_w$ matrix is then input in the `multilevel` function.

One or two-factor analyses are available.

Value

withinVariation simply returns the $X_w$ within matrix, which can be input in the other multivariate approaches already implemented in mixOmics (i.e. spls or splsda, see `multilevel`, but also `pca` or `ipca`).

Examples

```r
## Example: one-factor analysis matrix decomposition
#--------------------------------------------------------------
data(vac18)
X <- vac18$genes
# in design we only need to mention the repeated measurements to split the one level variation
design <- data.frame(sample = vac18$sample)

Xw <- withinVariation(X = X, design = design)
# multilevel PCA
res.pca.1level <- pca(Xw, ncomp = 3)

# compare a normal PCA with a multilevel PCA for repeated measurements.
# note: PCA makes the assumptions that all samples are independent,
# so this analysis is flawed and you should use a multilevel PCA instead
res.pca <- pca(X, ncomp = 3)

# set up colors for plotIndiv
col.stim <- c("darkblue", "purple", "green4", "red3")
col.stim <- col.stim[as.numeric(vac18$stimulation)]

# plotIndiv comparing both PCA and PCA multilevel
plotIndiv(res.pca, ind.names = vac18$stimulation, group = col.stim)
title(main = 'PCA ')
plotIndiv(res.pca.1level, ind.names = vac18$stimulation, group = col.stim)
title(main = 'PCA multilevel')
```

**wrapper.rgcca**

MixOmics wrapper for Regularised Generalised Canonical Correlation Analysis (rgcca)

Description

Wrapper function to perform Regularized Generalised Canonical Correlation Analysis (rGCCA), a generalised approach for the integration of multiple datasets. For more details, see the help(rgcca) from the RGCCA package.
wrapper.rgcca

Usage

\[
\text{wrapper.rgcca}(X, \\
\text{design} = 1 - \text{diag}(\text{length}(X)), \\
\tau = \text{rep}(1, \text{length}(X)), \\
\text{ncomp} = 1, \\
\text{keepX}, \\
\text{scheme} = \text{"horst"}, \\
\text{scale} = \text{TRUE}, \\
\text{tol} = \text{.Machine}$\text{double.eps}, \\
\text{max.iter} = 1000, \\
\text{near.zero.var} = \text{FALSE}, \\
\text{all.outputs} = \text{TRUE})
\]

Arguments

- **X**: a list of data sets (called 'blocks') matching on the same samples. Data in the list should be arranged in samples x variables. NAs are not allowed.
- **design**: numeric matrix of size (number of blocks in \(X\)) x (number of blocks in \(X\)) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks using sGCCA; a value of 0 indicates no relationship, 1 is the maximum value. If \(Y\) is provided instead of \(indY\), the design matrix is changed to include relationships to \(Y\).
- **tau**: numeric vector of length the number of blocks in \(X\). Each regularization parameter will be applied on each block and takes the value between 0 and 1. If tau = "optimal" the shrinkage parameters are estimated for each block and each dimension using the Schafer and Strimmer (2005) analytical formula.
- **ncomp**: the number of components to include in the model. Default to 1.
- **keepX**: A vector of same length as \(X\). Each entry keepX[i] is the number of \(X[i]\)-variables kept in the model.
- **scheme**: Either "horst", "factorial" or "centroid" (Default: "horst").
- **scale**: Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
- **init**: Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of \(X\) with \(Y\) ("svd") or each block independently ("svd.single"). Default to "svd.single".
- **tol**: Convergence stopping value.
- **max.iter**: integer, the maximum number of iterations.
- **near.zero.var**: Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
- **all.outputs**: Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.
Details

This wrapper function performs rGCCA (see RGCCA) with \(1, \ldots, n\text{comp}\) components on each block data set. A supervised or unsupervised model can be run. For a supervised model, the \texttt{unmap} function should be used as an input data set. More details can be found on the package RGCCA.

Value

\texttt{wrapper.rgcca} returns an object of class "rgcca", a list that contains the following components:

- \texttt{data}: the input data set (as a list).
- \texttt{design}: the input design.
- \texttt{variates}: the sgcca components.
- \texttt{loadings}: the loadings for each block data set (outer weight vector).
- \texttt{loadings.star}: the loadings, standardised.
- \texttt{tau}: the input tau parameter.
- \texttt{scheme}: the input scheme.
- \texttt{ncomp}: the number of components included in the model for each block.
- \texttt{crit}: the convergence criterion.
- \texttt{AVE}: Indicators of model quality based on the Average Variance Explained (AVE): AVE(for one block), AVE(outer model), AVE(inner model).
- \texttt{names}: list containing the names to be used for individuals and variables.

More details can be found in the references.

# need to unmap the Y factor diet
Y = unmap(nutrimouse$diet)
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid, Y = Y)
# with this design, gene expression and lipids are connected to the diet factor
# design = matrix(c(0,0,1, 
# 0,0,1, 
# 1,1,0), ncol = 3, nrow = 3, byrow = TRUE)
# with this design, gene expression and lipids are connected to the diet factor
# and gene expression and lipids are also connected
design = matrix(c(0,1,1, 
1,0,1, 
1,1,0), ncol = 3, nrow = 3, byrow = TRUE)
#note: the tau parameter is the regularization parameter
wrap.result.rgcca = wrapper.rgcca(X = data, design = design, tau = c(1, 1, 0),
ncomp = 2,
scheme = "centroid")
#wrap.result.rgcca

Description

Wrapper function to perform Sparse Generalised Canonical Correlation Analysis (sGCCA), a generalised approach for the integration of multiple datasets. For more details, see the help(sgcca) from the RGCCA package.

Usage

wrapper.sgcca(
  X,
  design = 1 - diag(length(X)),
  penalty = NULL,
  ncomp = 1,
  keepX,
  scheme = "horst",
  mode = "canonical",
  scale = TRUE,
  init = "svd.single",
  tol = .Machine$double.eps,
  max.iter = 1000,
  near.zero.var = FALSE,
  all.outputs = TRUE
)
Arguments

- **X**
  a list of data sets (called 'blocks') matching on the same samples. Data in the list should be arranged in samples x variables. NAs are not allowed.

- **design**
  numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks using sGCCA; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.

- **penalty**
  numeric vector of length the number of blocks in X. Each penalty parameter will be applied on each block and takes the value between 0 (no variable selected) and 1 (all variables included).

- **ncomp**
  the number of components to include in the model. Default to 1.

- **keepX**
  A vector of same length as X. Each entry keepX[i] is the number of X[i]-variables kept in the model.

- **scheme**
  Either "horst", "factorial" or "centroid" (Default: "horst").

- **mode**
  character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.

- **scale**
  Logical. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

- **init**
  Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default to "svd.single".

- **tol**
  Convergence stopping value.

- **max.iter**
  integer, the maximum number of iterations.

- **near.zero.var**
  Logical, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE

- **all.outputs**
  Logical. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

This wrapper function performs sGCCA (see RGCCA) with 1,\ldots,ncomp components on each block data set. A supervised or unsupervised model can be run. For a supervised model, the unmap function should be used as an input data set. More details can be found on the package RGCCA.

Note that this function is the same as block.spls with different default arguments.

More details about the PLS modes in ?pls.

Value

wrapper.sgcca returns an object of class "sgcca", a list that contains the following components:

- **data**
  the input data set (as a list).

- **design**
  the input design.
variates the sgcca components.
loadings the loadings for each block data set (outer wieght vector).
loadings.star the laodings, standardised.
penalty the input penalty parameter.
scheme the input schme.
ncomp the number of components included in the model for each block.
crit the convergence criterion.
AVE Indicators of model quality based on the Average Variance Explained (AVE): AVE(for one block), AVE(outer model), AVE(inner model)..
names list containing the names to be used for individuals and variables.

More details can be found in the references.

yeast

**Yeast metabolomic study**

### Description

Two Saccharomyces Cerevisiae strains were compared under two different environmental conditions, 37 metabolites expression are measured.

### Usage

```r
data(yeast)
```

### Format

A list containing the following components:

- `list("data")` data matrix with 55 rows and 37 columns. Each row represents an experimental sample, and each column a single metabolite.
- `list("strain")` a factor containing the type of strain (MT or WT).
- `list("condition")` a factor containing the type of environmental condition (AER or ANA).
- `list("strain.condition")` a crossed factor between strain and condition.

### Details

In this study, two Saccharomyces cerevisiae strains were used - wild-type (WT) and mutant (MT), and were carried out in batch cultures under two different environmental conditions, aerobic (AER) and anaerobic (ANA) in standard mineral media with glucose as the sole carbon source. After normalization and pre processing, the metabolomic data results in 37 metabolites and 55 samples which include 13 MT-AER, 14 MT-ANA, 15 WT-AER and 13 WT-ANA samples

### Value

none
