Package ‘pwalign’

May 22, 2024

**Title**  Perform pairwise sequence alignments

**Description**  The two main functions in the package are pairwiseAlignment() and stringDist(). The former solves (Needleman-Wunsch) global alignment, (Smith-Waterman) local alignment, and (ends-free) overlap alignment problems. The latter computes the Levenshtein edit distance or pairwise alignment score matrix for a set of strings.

align-utils

Utility functions related to sequence alignment

Description

A variety of different functions used to deal with sequence alignments.

Usage

nedit(x) # also nmatch and nmismatch

mismatchTable(x, shiftLeft=0L, shiftRight=0L, ...)
mismatchSummary(x, ...)

## S4 method for signature 'AlignedXStringSet0'
coverage(x, shift=0L, width=NULL, weight=1L)

## S4 method for signature 'PairwiseAlignmentsSingleSubject'
coverage(x, shift=0L, width=NULL, weight=1L)

compareStrings(pattern, subject)

## S4 method for signature 'PairwiseAlignmentsSingleSubject'
consensusMatrix(x, 
as.prob=FALSE, shift=0L, width=NULL, 
baseOnly=FALSE, gapCode="-", endgapCode="-")
Align-Utils

Arguments

- **x**: A character vector or matrix, `XStringSet`, `XStringViews`, `PairwiseAlignments`, or list of FASTA records containing the equal-length strings.
  
- **shiftLeft**, **shiftRight**: Non-positive and non-negative integers respectively that specify how many preceding and succeeding characters to and from the mismatch position to include in the mismatch substrings.
  
- **...**: Further arguments to be passed to or from other methods.
  
- **weight**: An integer vector specifying how much each element in `x` counts.
  
- **pattern**, **subject**: The strings to compare. Can be of type character, `XString`, `XStringSet`, `AlignedXStringSet`, or, in the case of `pattern`, `PairwiseAlignments` object. If the first argument of `compareStrings()` (pattern) is a `PairwiseAlignments` object, then the second argument (subject) must be missing. In this case `compareStrings(x)` is equivalent to `compareStrings(pattern(x), subject(x))`.
  
- **as.prob**: If TRUE then probabilities are reported, otherwise counts (the default).
  
- **baseOnly**: TRUE or FALSE. If TRUE, the returned vector only contains frequencies for the letters in the "base" alphabet i.e. "A", "C", "G", "T" if `x` is a "DNA input", and "A", "C", "G", "U" if `x` is "RNA input". When `x` is a `BString` object (or an `XStringViews` object with a `BString` subject, or a `BStringSet` object), then the baseOnly argument is ignored.
  
- **gapCode**, **endgapCode**: The codes in the appropriate alphabet to use for the internal and end gaps.

Value

- **nedit()**: An integer vector of the same length as the input `PairwiseAlignments` object reporting the number of edits (i.e. nb of mismatches + nb of indels) for each alignment.
  
- **mismatchTable()**: A data.frame containing the positions and substrings of the mismatches for the `AlignedXStringSet` or `PairwiseAlignments` object.
  
- **mismatchSummary()**: A list of data.frame objects containing counts and frequencies of the mismatches for the `AlignedXStringSet` or `PairwiseAlignmentsSingleSubject` object.
  
- **compareStrings()**: Combines two equal-length strings that are assumed to be aligned into a single character string containing that replaces mismatches with "?", insertions with "+", and deletions with "-".

Examples

```r
## Compare two globally aligned strings
string1 <- "ACTTCACCAGCTCTGCCTGCAAACGTTGATC----AAAGG----AAACGCAAAGTTTTCAAG"
string2 <- "GTTTCACTACTTCTTCCGGTAAGTAAATATAAATATATAAAAATATAATTTCATC"
compareStrings(string1, string2)

## Create a consensus matrix
nw1 <- pairwiseAlignment(
  AAStringSet(c("HLDNLKGTF", "HVDDMPNAL")), AAString("SMDDTEKMSKL"),
  substitutionMatrix = "BLOSUM50", gapOpening = 3, gapExtension = 1)
consensusMatrix(nw1)

## Examine the consensus between the bacteriophage phi X174 genomes
data(phiX174Phage)
phageConsmat <- consensusMatrix(phiX174Phage, baseOnly = TRUE)
phageDiffs <- which(apply(phageConsmat, 2, max) < length(phiX174Phage))
phageDiffs
phageConsmat[,phageDiffs]
```

AlignedXStringSet-class

AlinedXStringSet and QualityAlignedXStringSet objects

Description

The AlignedXStringSet and QualityAlignedXStringSet classes are containers for storing an aligned XStringSet.

Details

Before we define the notion of alignment, we introduce the notion of “filled-with-gaps subsequence”. A “filled-with-gaps subsequence” of a string string1 is obtained by inserting 0 or any number of gaps in a subsequence of s1. For example L–A–ND and A–N–D are “filled-with-gaps subsequences” of LAND. An alignment between two strings string1 and string2 results in two strings (align1 and align2) that have the same length and are “filled-with-gaps subsequences” of string1 and string2.

For example, this is an alignment between LAND and LEAVES:

```
L–A
LEA
```

An alignment can be seen as a compact representation of one set of basic operations that transforms string1 into align1. There are 3 different kinds of basic operations: “insertions” (gaps in align1), “deletions” (gaps in align2), “replacements”. The above alignment represents the following basic operations:
AlignedXStringSet-class

insert E at pos 2
insert V at pos 4
insert E at pos 5
replace by S at pos 6 (N is replaced by S)
delete at pos 7 (D is deleted)

Note that "insert X at pos i" means that all letters at a position \( \geq i \) are moved 1 place to the right before X is actually inserted.

There are many possible alignments between two given strings string1 and string2 and a common problem is to find the one (or those ones) with the highest score, i.e. with the lower total cost in terms of basic operations.

Accessor methods

In the code snippets below, x is a AlignedXStringSet or QualityAlignedXStringSet object.

unaligned(x): The original string.
aligned(x, degap = FALSE): If degap = FALSE, the "filled-with-gaps subsequence" representing the aligned substring. If degap = TRUE, the "gap-less subsequence" representing the aligned substring.
ranges(x): The bounds of the aligned substring.
start(x): The start of the aligned substring.
end(x): The end of the aligned substring.
width(x): The width of the aligned substring, ignoring gaps.
indel(x): The positions, in the form of an IRanges object, of the insertions or deletions (depending on what x represents).
nindel(x): A two-column matrix containing the length and sum of the widths for each of the elements returned by indel.
length(x): The length of the aligned(x).
nchar(x): The nchar of the aligned(x).
alphabet(x): Equivalent to alphabet(unaligned(x)).
as.character(x): Converts aligned(x) to a character vector.
toString(x): Equivalent to toString(as.character(x)).

Subsetting methods

x[i]: Returns a new AlignedXStringSet or QualityAlignedXStringSet object made of the selected elements.
rep(x, times): Returns a new AlignedXStringSet or QualityAlignedXStringSet object made of the repeated elements.

aligned(alignedPattern)
as.character(alignedPattern)
nchar(alignedPattern)
```

---

**Description**

The InDel class is a container for storing insertion and deletion information.

**Details**

This is a generic class that stores any insertion and deletion information.

**Accessor methods**

In the code snippets below, `x` is an InDel object.

- `insertion(x)`: The insertion information.
- `deletion(x)`: The deletion information.

**Examples**

```r
pa <- PairwiseAlignments("-PA--W-HEAE", "HEAGAWGHE-E")
pa_indel <- indel(pa) # an InDel object
insertion(pa_indel)
deletion(pa_indel)
```
pairwiseAlignment

**Optimal Pairwise Alignment**

**Description**

Solves (Needleman-Wunsch) global alignment, (Smith-Waterman) local alignment, and (ends-free) overlap alignment problems.

**Usage**

```r
two_alignment(pattern, subject, ...) 
## S4 method for signature 'ANY,ANY'
two_alignment(pattern, subject, 
  patternQuality=PhredQuality(22L), 
  subjectQuality=PhredQuality(22L), 
  type="global", 
  substitutionMatrix=NULL, fuzzyMatrix=NULL, 
  gapOpening=10, gapExtension=4, 
  scoreOnly=FALSE)
```

**Arguments**

- **pattern**: a character vector or `XStringSet` derivative of any length, or an `XString` derivative.
- **subject**: a character vector or `XStringSet` derivative of length 1 or length(`pattern`), or an `XString` derivative.
- **patternQuality**, **subjectQuality**: objects of class `XStringQuality` representing the respective quality scores for `pattern` and `subject` that are used in a quality-based method for generating a substitution matrix. These two arguments are ignored if `!is.null(substitutionMatrix)` or if its respective string set (`pattern`, `subject`) is of class `QualityScaledXStringSet`.
- **type**: type of alignment. One of "global", "local", "overlap", "global-local", and "local-global" where "global" = align whole strings with end gap penalties, "local" = align string fragments, "overlap" = align whole strings without end gap penalties, "global-local" = align whole strings in `pattern` with consecutive subsequence of `subject`, "local-global" = align consecutive subsequence of `pattern` with whole strings in `subject`. 

```r
two_alignment(pattern, subject, 
  type="global", 
  substitutionMatrix=NULL, fuzzyMatrix=NULL, 
  gapOpening=10, gapExtension=4, 
  scoreOnly=FALSE)
```
substitutionMatrix

Substitution matrix representing the fixed substitution scores for an alignment. It cannot be used in conjunction with patternQuality and subjectQuality arguments.

fuzzyMatrix

Fuzzy match matrix for quality-based alignments. It takes values between 0 and 1; where 0 is an unambiguous mismatch, 1 is an unambiguous match, and values in between represent a fraction of "matchiness". (See details section below.)

gapOpening

The cost for opening a gap in the alignment.

gapExtension

The incremental cost incurred along the length of the gap in the alignment.

scoreOnly

Logical to denote whether or not to return just the scores of the optimal pairwise alignment.

Details

Quality-based alignments are based on the paper the Bioinformatics article by Ketil Malde listed in the Reference section below. Let $\epsilon_i$ be the probability of an error in the base read. For "Phred" quality measures $Q$ in $[0, 99]$, these error probabilities are given by $\epsilon_i = 10^{-Q/10}$. For "Solexa" quality measures $Q$ in $[-5, 99]$, they are given by $\epsilon_i = 1 - 1/(1 + 10^{-Q/10})$. Assuming independence within and between base reads, the combined error probability of a mismatch when the underlying bases do match is $\epsilon_c = \epsilon_1 + \epsilon_2 - (n/(n-1)) * \epsilon_1 * \epsilon_2$, where $n$ is the number of letters in the underlying alphabet (i.e. $n = 4$ for DNA input, $n = 20$ for amino acid input, otherwise $n$ is the number of distinct letters in the input). Using $\epsilon_c$, the substitution score is given by $b * \log_2(\gamma_{x,y} * (1 - \epsilon_c)^n + (1 - \gamma_{x,y}) * \epsilon_c * (n/(n-1)))$, where $b$ is the bit-scaling for the scoring and $\gamma_{x,y}$ is the probability that characters $x$ and $y$ represents the same underlying information (e.g. using IUPAC, $\gamma_{A,A} = 1$ and $\gamma_{A,N} = 1/4$. In the arguments listed above fuzzyMatch represents $\gamma_{x,y}$ and patternQuality and subjectQuality represents $\epsilon_1$ and $\epsilon_2$ respectively.

If scoreOnly == FALSE, a pairwise alignment with the maximum alignment score is returned. If more than one pairwise alignment produces the maximum alignment score, then the alignment with the smallest initial deletion whose mismatches occur before its insertions and deletions is chosen. For example, if pattern = "AGTA" and subject = "AACTAACTA", then the alignment pattern: [1] AG-TA; subject: [1] AACTA is chosen over pattern: [1] A-GTA; subject: [1] AACTA or pattern: [1] AG-TA; subject: [5] AACTA if they all achieve the maximum alignment score.

Value

If scoreOnly == FALSE (the default), the function returns a PairwiseAlignmentsSingleSubject object (if a single subject was supplied) or a PairwiseAlignments object (if more than one subject was supplied). In both cases, the returned object contains $N$ optimal pairwise alignments where $N$ is the number of supplied patterns, that is, $N = \text{length(pattern)}$ if pattern is a character vector or XStringSet derivative, or $N = 1$ if it’s an XString derivative. If more than one subject was supplied, the alignments in the returned PairwiseAlignments object are obtained by aligning pattern[[1]] to subject[[1]], pattern[[2]] to subject[[2]], pattern[[3]] to subject[[3]], etc...

If scoreOnly == TRUE, a numeric vector containing the scores for the $N$ optimal pairwise alignments is returned.
pairwiseAlignment

Note

Use `matchPattern` or `vmatchPattern` if you need to find all the occurrences (eventually with indels) of a given pattern in a reference sequence or set of sequences.

Use `matchPDict` if you need to match a (big) set of patterns against a reference sequence.

Examples

```r
## Nucleotide global, local, and overlap alignments
s1 <- DNAString("ACTTCACGGCTCCCTGCGGTAAGTTGAGTCAAAGGAAACGCAAAGTTTTCAAG")
s2 <- DNAString("GTTTCACTACTTCCTTTGCAGTAAATATAAATAATAATAATAATAATAATAATAATAATAATAATAATAATAATAATGTTT")

# First use a fixed substitution matrix
mat <- nucleotideSubstitutionMatrix(match = 1, mismatch = -3, baseOnly = TRUE)
globalAlign <- pairwiseAlignment(s1, s2, substitutionMatrix = mat,
gapOpening = 5, gapExtension = 2)
localAlign <- pairwiseAlignment(s1, s2, type = "local", substitutionMatrix = mat,
gapOpening = 5, gapExtension = 2)
overlapAlign <- pairwiseAlignment(s1, s2, type = "overlap", substitutionMatrix = mat,
gapOpening = 5, gapExtension = 2)

# Then use quality-based method for generating a substitution matrix
pairwiseAlignment(s1, s2,
    patternQuality = SolexaQuality(rep(c(22L, 12L), times = c(36, 18))),
    subjectQuality = SolexaQuality(rep(c(22L, 12L), times = c(40, 20))),
    scoreOnly = TRUE)

# Now assume can't distinguish between C/T and G/A
pairwiseAlignment(s1, s2,
```
PairwiseAlignments-class

PairwiseAlignments, PairwiseAlignmentsSingleSubject, and PairwiseAlignmentsSingleSubjectSummary objects

Description

The PairwiseAlignments class is a container for storing a set of pairwise alignments. The PairwiseAlignmentsSingleSubject class is a container for storing a set of pairwise alignments with a single subject. The PairwiseAlignmentsSingleSubjectSummary class is a container for storing the summary of a set of pairwise alignments.

Usage

## Constructors:
## When subject is missing, pattern must be of length 2
## S4 method for signature 'XString,XString'
PairwiseAlignments(pattern, subject,
  type = "global", substitutionMatrix = NULL, gapOpening = 0, gapExtension = 1)
## S4 method for signature 'XStringSet,missing'
PairwiseAlignments(pattern, subject,
  type = "global", substitutionMatrix = NULL, gapOpening = 0, gapExtension = 1)
## S4 method for signature 'character,character'
PairwiseAlignments(pattern, subject,
  type = "global", substitutionMatrix = NULL, gapOpening = 0, gapExtension = 1,
  baseClass = "BString")
## S4 method for signature 'character,missing'
PairwiseAlignments(pattern, subject,
  type = "global", substitutionMatrix = NULL, gapOpening = 0, gapExtension = 1,
  baseClass = "BString")
Arguments

- **pattern**: a character vector of length 1 or 2, an `XString`, or an `XStringSet` object of length 1 or 2.
- **subject**: a character vector of length 1 or an `XString` object.
- **type**: type of alignment. One of "global", "local", "overlap", "global-local", and "local-global" where "global" = align whole strings with end gap penalties, "local" = align string fragments, "overlap" = align whole strings without end gap penalties, "global-local" = align whole strings in pattern with consecutive subsequence of subject, "local-global" = align consecutive subsequence of pattern with whole strings in subject.

- **substitutionMatrix**: substitution matrix for the alignment. If NULL, the diagonal values and off-diagonal values are set to 0 and 1 respectively.
- **gapOpening**: the cost for opening a gap in the alignment.
- **gapExtension**: the incremental cost incurred along the length of the gap in the alignment.
- **baseClass**: the base `XString` class to use in the alignment.

Details

Before we define the notion of alignment, we introduce the notion of "filled-with-gaps subsequence". A "filled-with-gaps subsequence" of a string `s1` is obtained by inserting 0 or any number of gaps in a subsequence of `s1`. For example L-A–ND and A–N-D are "filled-with-gaps subsequences" of LAND. An alignment between two strings `s1` and `s2` results in two strings (`align1` and `align2`) that have the same length and are "filled-with-gaps subsequences" of `s1` and `s2`.

For example, this is an alignment between LAND and LEAVES:

```
L-A
LEA
```

An alignment can be seen as a compact representation of one set of basic operations that transforms `s1` into `align1`. There are 3 different kinds of basic operations: "insertions" (gaps in `align1`), "deletions" (gaps in `align2`), "replacements". The above alignment represents the following basic operations:

- insert E at pos 2
- insert V at pos 4
- insert E at pos 5
- replace by S at pos 6 (N is replaced by S)
- delete at pos 7 (D is deleted)

Note that "insert X at pos i" means that all letters at a position >= i are moved 1 place to the right before X is actually inserted.

There are many possible alignments between two given strings `s1` and `s2` and a common problem is to find the one (or those ones) with the highest score, i.e. with the lower total cost in terms of basic operations.
Object extraction methods

In the code snippets below, `x` is a PairwiseAlignments object, except otherwise noted.

alignedPattern(x), alignedSubject(x): Extract the aligned patterns or subjects as an XStringSet object. The 2 objects returned by alignedPattern(x) and alignedSubject(x) are guaranteed to have the same shape (i.e. same length() and width()).

pattern(x), subject(x): Extract the aligned patterns or subjects as an AlignedXStringSet object.

summary(object, ...): Generates a summary for the PairwiseAlignments object.

General information methods

In the code snippets below, `x` is a PairwiseAlignments object, except otherwise noted.

alphabet(x): Equivalent to alphabet(unaligned(subject(x))).

length(x): The common length of alignedPattern(x) and alignedSubject(x). There is a method for PairwiseAlignmentsSingleSubjectSummary as well.

type(x): The type of the alignment ("global", "local", "overlap", "global-local", or "local-global"). There is a method for PairwiseAlignmentsSingleSubjectSummary as well.

Aligned sequence methods

In the code snippets below, `x` is a PairwiseAlignmentsSingleSubject object, except otherwise noted.

aligned(x, degap = FALSE, gapCode="-", endgapCode="-"): If degap = FALSE, "align" the alignments by returning an XStringSet object containing the aligned patterns without insertions. If degap = TRUE, returns aligned(pattern(x), degap=TRUE). The gapCode and endgapCode arguments denote the code in the appropriate alphabet to use for the internal and end gaps.

as.character(x): Equivalent to as.character(alignedPattern(x)).

as.matrix(x): Returns an "exploded" character matrix representation of aligned(x).

toString(x): Equivalent to toString(as.character(x)).

Subject position methods

In the code snippets below, `x` is a PairwiseAlignmentsSingleSubject object, except otherwise noted.

consensusMatrix(x, as.prob=FALSE, baseOnly=FALSE, gapCode="-", endgapCode="-"): See 'consensusMatrix' for more information.

consensusString(x): See 'consensusString' for more information.

coverage(x, shift=0L, width=NULL, weight=1L): See 'coverage,PairwiseAlignmentsSingleSubject-method' for more information.

Views(subject, start=NULL, end=NULL, width=NULL, names=NULL): The XStringViews object that represents the pairwise alignments along unaligned(subject(subject)). The start and end arguments must be either NULL/NA or an integer vector of length 1 that denotes the offset from start(subject(subject)).
PairwiseAlignments-class

Numeric summary methods

In the code snippets below, x is a PairwiseAlignments object, except otherwise noted.

nchar(x): The nchar of the aligned(pattern(x)) and aligned(subject(x)). There is a method for PairwiseAlignmentsSingleSubjectSummary as well.

insertion(x): An CompressedIRangesList object containing the locations of the insertions from the perspective of the pattern.

deletion(x): An CompressedIRangesList object containing the locations of the deletions from the perspective of the pattern.

indel(x): An InDel object containing the locations of the insertions and deletions from the perspective of the pattern.

nindel(x): An InDel object containing the number of insertions and deletions.

score(x): The score of the alignment. There is a method for PairwiseAlignmentsSingleSubjectSummary as well.

Subsetting methods

x[i]: Returns a new PairwiseAlignments object made of the selected elements.

rep(x, times): Returns a new PairwiseAlignments object made of the repeated elements.

Write a PairwiseAlignments object to a file

Description
The writePairwiseAlignments function writes a PairwiseAlignments object to a file. Only the "pair" format is supported at the moment.

Usage
writePairwiseAlignments(x, file=",", Matrix=NA, block.width=50)

Arguments
- **x**: A PairwiseAlignments object, typically returned by the pairwiseAlignment function.
- **file**: A connection, or a character string naming the file to print to. If "" (the default), writePairwiseAlignments prints to the standard output connection (aka the console) unless redirected by sink. If it is "|cmd", the output is piped to the command given by cmd, by opening a pipe connection.
- **Matrix**: A single string containing the name of the substitution matrix (e.g. "BLOSUM50") used for the alignment. See the substitutionMatrix argument of the pairwiseAlignment function for the details. See ?substitution_matrices for a list of predefined substitution matrices available in the pwalign package.
- **block.width**: A single integer specifying the maximum number of sequence letters (including the "." letter, which represents gaps) per line.

Details
The "pair" format is one of the numerous pairwise sequence alignment formats supported by the EMBOSS software. See http://emboss.sourceforge.net/docs/themes/AlignFormats.html for a brief (and rather informal) description of this format.

Value
Nothing (invisible NULL).

Note
This brief description of the "pair" format suggests that it is best suited for global pairwise alignments, because, in that case, the original pattern and subject sequences can be inferred (by just removing the gaps).

However, even though the "pair" format can also be used for non global pairwise alignments (i.e. for global-local, local-global, and local pairwise alignments), in that case the original pattern and subject sequences cannot be inferred. This is because the alignment written to the file doesn’t necessarily span the entire pattern (if type(x) is local-global or local) or the entire subject (if type(x) is global-local or local).
As a consequence, the `writePairwiseAlignments` function can be used on a `PairwiseAlignments` object `x` containing non global alignments (i.e. with `type(x) != "global"`), but with the 2 following caveats:

1. The type of the alignments (`type(x)`) is not written to the file.
2. The original pattern and subject sequences cannot be inferred. Furthermore, there is no way to infer their lengths (because we don’t know whether they were trimmed or not).

Also note that the `pairwiseAlignment` function interprets the `gapOpening` and `gapExtension` arguments differently than most other alignment tools. As a consequence the values of the `Gap_penalty` and `Extend_penalty` fields written to the file are not the same as the values that were passed to the `gapOpening` and `gapExtension` arguments. With the following relationship:

- Gap_penalty = gapOpening + gapExtension
- Extend_penalty = gapExtension

phiX174Phage

Versions of bacteriophage phiX174 complete genome and sample short reads

Description

Six versions of the complete genome for bacteriophage \(\phi\) X174 as well as a small number of Solexa short reads, qualities associated with those short reads, and counts for the number times those short reads occurred.

Format

phiX174Phage: A DNAStringSet containing the following six naturally occurring versions of the bacteriophage \(\phi\) X174 genome cited in Smith et al.:

1. Genbank: The version of the genome from GenBank (NC_001422.1, GI:9626372).
2. RF70s: A preparation of $\phi$X double-stranded replicative form (RF) of DNA by Clyde A. Hutchison III from the late 1970s.
3. SS78: A preparation of $\phi$X virion single-stranded DNA from 1978.
4. Bull: The sequence of wild-type $\phi$X used by Bull et al.
5. G’97: The $\phi$X replicative form (RF) of DNA from Bull et al.
6. NEB’03: A $\phi$X replicative form (RF) of DNA from New England BioLabs (NEB).

srPhiX174: A DNAStringSet containing short reads from a Solexa machine.
quPhiX174: A BStringSet containing Solexa quality scores associated with srPhiX174.
wtPhiX174: An integer vector containing counts associated with srPhiX174.

type="global-local")

summary(alignPhiX174, weight=wtPhiX174)
Description
Calculates the percent sequence identity for a pairwise sequence alignment.

Usage
`pid(x, type="PID1")`

Arguments
- `x`: a `PairwiseAlignments` object.
- `type`: one of percent sequence identity. One of "PID1", "PID2", "PID3", and "PID4". See Details for more information.

Details
Since there is no universal definition of percent sequence identity, the `pid` function calculates this statistic in the following types:

  "PID1": \(100 \times \frac{\text{identical positions}}{\text{aligned positions} + \text{internal gap positions}}\)

  "PID2": \(100 \times \frac{\text{identical positions}}{\text{aligned positions}}\)

  "PID3": \(100 \times \frac{\text{identical positions}}{\text{length shorter sequence}}\)

  "PID4": \(100 \times \frac{\text{identical positions}}{\text{average length of the two sequences}}\)

Value
A numeric vector containing the specified sequence identity measures.

**predefined_scoring_matrices**

*Predefined scoring matrices*

**Description**

Predefined scoring matrices for nucleotide and amino acid alignments.

**Usage**

```r
data(BLOSUM45)
data(BLOSUM50)
data(BLOSUM62)
data(BLOSUM80)
data(BLOSUM100)
data(PAM30)
data(PAM40)
data(PAM70)
data(PAM120)
data(PAM250)
```

**Format**

The BLOSUM and PAM matrices are square symmetric matrices with integer coefficients, whose row and column names are identical and unique: each name is a single letter representing a nucleotide or an amino acid.

**Details**

The BLOSUM and PAM matrices are not unique. For example, the definition of the widely used BLOSUM62 matrix varies depending on the source, and even a given source can provide different versions of "BLOSUM62" without keeping track of the changes over time. NCBI provides many

The BLOSUM45, BLOSUM62, BLOSUM80, PAM30 and PAM70 matrices were taken from NCBI stand-alone BLAST software.

The BLOSUM50, BLOSUM100, PAM40, PAM120 and PAM250 matrices were taken from ftp://ftp.ncbi.nih.gov/blast/matrices/

stringDist

String Distance/Alignment Score Matrix

Description

Computes the Levenshtein edit distance or pairwise alignment score matrix for a set of strings.
Usage

```r
stringDist(x, method = "levenshtein", ignoreCase = FALSE, diag = FALSE, upper = FALSE, ...)
## S4 method for signature 'XStringSet'
stringDist(x, method = "levenshtein", ignoreCase = FALSE, diag = FALSE,
upper = FALSE, type = "global", quality = PhredQuality(22L),
substitutionMatrix = NULL, fuzzyMatrix = NULL, gapOpening = 0,
gapExtension = 1)
## S4 method for signature 'QualityScaledXStringSet'
stringDist(x, method = "quality", ignoreCase = FALSE,
diag = FALSE, upper = FALSE, type = "global", substitutionMatrix = NULL,
fuzzyMatrix = NULL, gapOpening = 0, gapExtension = 1)
```

Arguments

- `x`: a character vector or an `XStringSet` object.
- `method`: calculation method. One of "levenshtein", "hamming", "quality", or "substitutionMatrix".
- `ignoreCase`: logical value indicating whether to ignore case during scoring.
- `diag`: logical value indicating whether the diagonal of the matrix should be printed by `print.dist`.
- `upper`: logical value indicating whether the upper triangle of the matrix should be printed by `print.dist`.
- `type`: (applicable when `method = "quality"` or `method = "substitutionMatrix"`). type of alignment. One of "global", "local", and "overlap", where "global" = align whole strings with end gap penalties, "local" = align string fragments, "overlap" = align whole strings without end gap penalties.
- `quality`: (applicable when `method = "quality"`). object of class `XStringQuality` representing the quality scores for `x` that are used in a quality-based method for generating a substitution matrix.
- `substitutionMatrix`: (applicable when `method = "substitutionMatrix"`). symmetric matrix representing the fixed substitution scores in the alignment.
- `fuzzyMatrix`: (applicable when `method = "quality"`). fuzzy match matrix for quality-based alignments. It takes values between 0 and 1; where 0 is an unambiguous mismatch, 1 is an unambiguous match, and values in between represent a fraction of "matchiness".
- `gapOpening`: (applicable when `method = "quality"` or `method = "substitutionMatrix"`). penalty for opening a gap in the alignment.
- `gapExtension`: (applicable when `method = "quality"` or `method = "substitutionMatrix"`). penalty for extending a gap in the alignment.
- `...`: optional arguments to generic function to support additional methods.

Details

When `method = "hamming"`, uses the underlying `neditStartingAt` code to calculate the distances, where the Hamming distance is defined as the number of substitutions between two strings of equal length. Otherwise, uses the underlying `pairwiseAlignment` code to compute the distance/alignment score matrix.
substitution_matrices

Utilities to generate substitution matrices

Description

Utilities to generate substitution matrices.

Usage

nucleotideSubstitutionMatrix(match=1, mismatch=0, baseOnly=FALSE, type="DNA", symmetric=TRUE)

qualitySubstitutionMatrices(fuzzyMatch=c(0, 1), alphabetLength=4L, qualityClass="PhredQuality", bitScale=1)

errorSubstitutionMatrices(errorProbability, fuzzyMatch=c(0, 1), alphabetLength=4L, bitScale=1)
Arguments

- **match**: the scoring for a nucleotide match.
- **mismatch**: the scoring for a nucleotide mismatch.
- **baseOnly**: TRUE or FALSE. If TRUE, only uses the letters in the "base" alphabet i.e. "A", "C", "G", "T".
- **type**: either "DNA" or "RNA".
- **symmetric**: TRUE or FALSE. Default is TRUE. If FALSE, the resulting matrix will be asymmetric.
- **fuzzyMatch**: a named or unnamed numeric vector representing the base match probability.
- **errorProbability**: a named or unnamed numeric vector representing the error probability.
- **alphabetLength**: an integer representing the number of letters in the underlying string alphabet. For DNA and RNA, this would be 4L. For Amino Acids, this could be 20L.
- **qualityClass**: a character string of "PhredQuality", "SolexaQuality", or "IlluminaQuality".
- **bitScale**: a numeric value to scale the quality-based substitution matrices. By default, this is 1, representing bit-scale scoring.

Details

The quality matrices computed in `qualitySubstitutionMatrices` are based on the paper by Ketil Malde. Let $\epsilon_i$ be the probability of an error in the base read. For "Phred" quality measures $Q$ in $[0, 99]$, these error probabilities are given by $\epsilon_i = 10^{-Q/10}$. For "Solexa" quality measures $Q$ in $[-5, 99]$, they are given by $\epsilon_i = 1 - 1/(1+10^{-Q/10})$. Assuming independence within and between base reads, the combined error probability of a mismatch when the underlying bases do match is $\epsilon_c = \epsilon_1 + \epsilon_2 - (n/(n-1)) \times \epsilon_1 \times \epsilon_2$, where $n$ is the number of letters in the underlying alphabet. Using $\epsilon_c$, the substitution score is given by when two bases match is given by $b \times \log_2(\gamma_{x,y} \times (1 - \epsilon_c) \times n + (1 - \gamma_{x,y}) \times \epsilon_c \times (n/(n-1)))$, where $b$ is the bit-scaling for the scoring and $\gamma_{x,y}$ is the probability that characters $x$ and $y$ represents the same underlying information (e.g. using IUPAC, $\gamma_{A,A} = 1$ and $\gamma_{A,N} = 1/4$. In the arguments listed above fuzzyMatch represents $\gamma_{x,y}$ and errorProbability represents $\epsilon_i$.

Value

A matrix.

Author(s)

P. Aboyoun, with contribution from Albert Vill (support for asymmetric matrices in nucleotideSubstitutionMatrix())

Examples

s1 <- DNAString("ACTTCACCAGCTCCCTGGCGGTAAGTTGATCAAAAGAAACGCAAAGTTTTCAAG")
s2 <- DNAString("GTTTCACTACTTCTTTCCGGTAAAGTTATATATAATAAAAAATATTTTTCATC")
s3 <- DNAString("NCTTCRCCAGCTCCCTGGGTAAGTTGATCAAAGVAAACGCAAAGTTNTCAAG")

## Fit a global pairwise alignment using edit distance scoring:
nsn <- nucleotideSubstitutionMatrix(0, -1, TRUE)
pairwiseAlignment(s1, s2, substitutionMatrix=nsn,
                  gapOpening=0, gapExtension=1)

## Align sequences using an asymmetric substitution matrix.
# The asymmetry of the matrix means that the query sequence is not
# penalized for ambiguous bases in the subject / consensus sequence:
ansm <- nucleotideSubstitutionMatrix(symmetric=FALSE)
ansm["M", c("A","C","G","T")]
# A C G T
# 0.5 0.5 0.0 0.0
ansm[c("A","C","G","T"), "M"]
# A C G T
# 1 1 0 0
ansm["M", "H"]
# 1
ansm["H", "M"]
# 0.6666667

## Due to this asymmetry, the order of the sequences is important:
pairwiseAlignment(s1, s3, substitutionMatrix=ansm)
pairwiseAlignment(s3, s1, substitutionMatrix=ansm)

## Examine quality-based match and mismatch bit scores for DNA/RNA
## strings in pairwiseAlignment. By default patternQuality and
## subjectQuality are PhredQuality(22L):
qualityMatrices <- qualitySubstitutionMatrices()
qualityMatrices["22", "22", "1"]
qualityMatrices["22", "22", "0"]
pairwiseAlignment(s1, s2)

## Get the substitution scores when the error probability is 0.1:
subscores <- errorSubstitutionMatrices(errorProbability=0.1)
submat <- matrix(subscores[, , "0"], 4, 4)
diag(submat) <- subscores[, , "1"]
dimnames(submat) <- list(DNA_ALPHABET[1:4], DNA_ALPHABET[1:4])
submat
pairwiseAlignment(s1, s2, substitutionMatrix=submat)
