Package ‘singscore’

May 18, 2024

Type Package
Title Rank-based single-sample gene set scoring method
Version 1.24.0
Description A simple single-sample gene signature scoring method that uses rank-based
    statistics to analyze the sample's gene expression profile. It scores the expression activities of
gene sets at a single-sample level.

Index 29
generateNull

**Description**

This function generates a number of random gene sets that have the same number of genes as the scored gene set. It scores each random gene set and returns a matrix of scores for all samples. The empirical scores are used to calculate the empirical p-values and plot the null distribution. The implementation uses `BiocParallel::bplapply()` for easy access to parallel backends. Note that one should pass the same values to the `upSet`, `downSet`, `centerScore` and `bidirectional` arguments as what they provide for the `simpleScore()` function to generate a proper null distribution.

**Usage**

```r
generateNull(
  upSet,
  downSet = NULL,
  rankData,
  subSamples = NULL,
  centerScore = TRUE,
  knownDirection = TRUE,
  B = 1000,
  ncores = 1,
  seed = sample.int(1e+06, 1),
  useBPPARAM = NULL
)
```

```r
## S4 method for signature 'vector,ANY'
generateNull(
  upSet,
  downSet = NULL,
  rankData,
  subSamples = NULL,
  centerScore = TRUE,
  knownDirection = TRUE,
  B = 1000,
  ncores = 1,
  seed = sample.int(1e+06, 1),
  useBPPARAM = NULL
)
```

```r
## S4 method for signature 'GeneSet,ANY'
generateNull(
  upSet,
  downSet = NULL,
  rankData,
  subSamples = NULL,
  centerScore = TRUE,
  knownDirection = TRUE,
  B = 1000,
  ncores = 1,
  seed = sample.int(1e+06, 1),
)```
generateNull =

useBPPARAM = NULL

## S4 method for signature 'vector,vector'
genenerateNull(
  upSet,
  downSet = NULL,
  rankData,
  subSamples = NULL,
  centerScore = TRUE,
  knownDirection = TRUE,
  B = 1000,
  ncores = 1,
  seed = sample.int(1e+06, 1),
  useBPPARAM = NULL
)

## S4 method for signature 'GeneSet,GeneSet'
genenerateNull(
  upSet,
  downSet = NULL,
  rankData,
  subSamples = NULL,
  centerScore = TRUE,
  knownDirection = TRUE,
  B = 1000,
  ncores = 1,
  seed = sample.int(1e+06, 1),
  useBPPARAM = NULL
)

Arguments

upSet A GeneSet object or character vector of gene IDs of up-regulated gene set or a
gene set where the nature of genes is not known
downSet A GeneSet object or character vector of gene IDs of down-regulated gene set or
NULL where only a single gene set is provided
rankData A matrix object, ranked gene expression matrix data generated using the rankGenes()function (make sure this matrix is not modified, see details)
subSamples A vector of sample labels/indices that will be used to subset the rankData matrix. All samples will be scored if not provided
centerScore A Boolean, specifying whether scores should be centered around 0, default as TRUE. Note: scores never centered if knownDirection = FALSE
knownDirection A boolean, determining whether the gene set should be considered to be direction-al or not. A gene set is directional if the type of genes in it are known i.e. up- or down-regulated. This should be set to TRUE if the gene set is composed of both up- AND down-regulated genes. Defaults to TRUE. This parameter becomes irrelevant when both upSet(Colc) and downSet(Colc) are provided.
**generateNull_intl**

- **B** integer, the number of permutation repeats or the number of random gene sets to be generated, default as 1000
- **ncores** integer, the number of CPU cores the function can use
- **seed** integer, set the seed for randomisation
- **useBPPARAM** the backend the function uses, if NULL is provided, the function uses the default parallel backend which is the first on the list returned by `BiocParallel::registered()` i.e `BiocParallel::registered()[[1]]` for your machine. It can be changed explicitly by passing a BPPARAM

**Value**

A matrix of empirical scores for all samples

**Author(s)**

Ruqian Lyu

**See Also**

Post about BiocParallel browseVignettes("BiocParallel")

**Examples**

```r
ranked <- rankGenes(toy_expr_se)
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)

# find out what backends can be registered on your machine
BiocParallel::registered()
# the first one is the default backend
# ncores = ncores <- parallel::detectCores() - 2
permuteResult = generateNull(upSet = toy_gs_up, downSet = toy_gs_dn, ranked, centerScore = TRUE, B = 10, seed = 1, ncores = 1 )
```

---

**generateNull_intl**  
*Permutation test for the derived scores of each sample*

**Description**

This function generates a number of random gene sets that have the same number of genes as the scored gene set. It scores each random gene set and returns a matrix of scores for all samples. The empirical scores are used to calculate the empirical p-values and plot the null distribution. The implementation uses `BiocParallel::bplapply()` for easy access to parallel backends. Note that one should pass the same values to the upSet, downSet, centerScore and knownDirection arguments as what they provide for the simpleScore() function to generate a proper null distribution.
generateNull_intl(  
  upSet,  
  downSet = NULL,  
  rankData,  
  subSamples = NULL,  
  centerScore = TRUE,  
  knownDirection = TRUE,  
  B = 1000,  
  ncores = 1,  
  seed = sample.int(1e+06, 1),  
  useBPPARAM = NULL  
)

Arguments

downSet A GeneSet object, down regulated gene set

rankData matrix, outcome of function rankGenes()

centerScore A Boolean, specifying whether scores should be centered around 0, default as TRUE

knownDirection A boolean flag, it determines whether the scoring method should derive the scores in a directional manner when the gene signature only contains one set of gene set (passing the gene set via upSet). It is default as TRUE but one can set the argument to be FALSE to derive the score for a single gene set in an undirectional way. This parameter becomes irrelevant when both upSet and downSet are provided.

B integer, the number of permutation repeats or the number of random gene sets to be generated, default as 1,000

ncores integer, the number of CPU cores the function can use

seed integer, set the seed for randomisation

useBPPARAM the backend the function uses, if NULL is provided, the function uses the default parallel backend which is the first on the list returned by BiocParallel::registered() i.e BiocParallel::registered()[[1]] for your machine. It can be changed explicitly by passing a BPPARAM

Value

A matrix of empirical scores for all samples

Author(s)

Ruqian Lyu

getPvals

---

**getPvals**  
*Estimate the empirical p-values*

**Description**

With null distributions estimated using the `generateNull()` function, p-values are estimated using a one-tailed test. A minimum p-value of 1/B can be achieved with B permutations.

**Usage**

```r
getPvals(permuteResult, scoredf, subSamples = NULL)
```

**Arguments**

- `permuteResult`: A matrix, null distributions for each sample generated using the `generateNull()` function.
- `scoredf`: A dataframe, the scored results of samples under test generated using the `simpleScore()` function.
- `subSamples`: A vector of sample labels/indices that will be used to subset the score matrix. All samples will be scored if not provided.

**Value**

Estimated p-values for enrichment of the signature in each sample. A p-value of 1/B indicates that the estimated p-value is less than or equal to 1/B.

**Examples**

```r
ranked <- rankGenes(toy_expr_se)  
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)  
# find out what backends can be registered on your machine  
BiocParallel::registered()  
# the first one is the default backend, and it can be changed explicitly.  
# See vignette for more details  
permuteResult = generateNull(upSet = toy_gs_up, downSet = toy_gs_dn, ranked,  
B = 10, seed = 1, useBPPARAM = NULL)

# call the permutation function to generate the empirical scores  
# for B times.  
pvals <- getPvals(permuteResult, scoredf)
```
getStableGenes  Get a list of stably expressed genes

Description
Get a list of genes that are stably expressed in cancer and normal solid tissue.

Usage
getStableGenes(
  n_stable,
  type = c("carcinoma", "blood", "protein"),
  id = c("geneid", "ensembl")
)

Arguments
n_stable  numeric, number of stable genes to retrieve
type  character, type of stable genes requested, stable genes in "carcinoma" or stable
genes in "blood"
id  character, gene identifier required. This can be either "geneid" for symbols or
"ensembl" ensembl id

Value
a character vector with gene IDs sorted by their expected expression levels in the requested tissue

Examples
getStableGenes(5)
getStableGenes(5, id = 'ensembl')
getStableGenes(5, type = 'blood')

multiScore  single-sample gene-set scoring method for multiple signatures

Description
This function computes 'singscores' using a ranked gene expression matrix obtained from the
rankGenes() function and a GeneSetCollection object or a list of GeneSet objects. It returns a
list of two matrices containing the scores and dispersions. This function should be used when scor-
ring needs to be performed for multiple signatures. It is faster than applying simpleScore() across
the different signatures independently.
Usage

multiScore(
  rankData,
  upSetColc,
  downSetColc,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,GeneSetCollection,missing'
multiScore(
  rankData,
  upSetColc,
  downSetColc,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,GeneSetCollection,GeneSetCollection'
multiScore(
  rankData,
  upSetColc,
  downSetColc,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,list,missing'
multiScore(
  rankData,
  upSetColc,
  downSetColc,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,list,list'
multiScore(
  rankData,
  upSetColc,
  downSetColc,
multiscore
downSetColc,
subSamples = NULL,
centerScore = TRUE,
dispersionFun = mad,
knownDirection = TRUE
)

Arguments

rankData  A matrix object, ranked gene expression matrix data generated using the rankGenes() function (make sure this matrix is not modified, see details)

upSetColc  A GeneSetCollection object, a list of GeneSet objects, or a list of character vectors of up-regulated (or mixed, see simpleScore) gene sets.

downSetColc  A GeneSetCollection object, a list of GeneSet objects, or a list of character vectors of down-regulated gene sets. NULL otherwise. Names of gene sets within this collection/list should be the same as those of the upSetColc

subSamples  A vector of sample labels/indices that will be used to subset the rankData matrix. All samples will be scored if not provided

centerScore  A Boolean, specifying whether scores should be centered around 0, default as TRUE. Note: scores never centered if knownDirection = FALSE

dispersionFun  A function, dispersion function with default being mad

knownDirection  A boolean, determining whether the gene set should be considered to be directional or not. A gene set is directional if the type of genes in it are known i.e. up- or down-regulated. This should be set to TRUE if the gene set is composed of both up- AND down-regulated genes. Defaults to TRUE. This parameter becomes irrelevant when both upSet(Colc) and downSet(Colc) are provided.

Value

A list of two matrices containing the scores and dispersions

See Also

rank "GeneSet"

Examples

ranked <- rankGenes(toy_expr_se)
GSEABase::setName(toy_gs_up) = "toy_gs_up"
GSEABase::setName(toy_gs_dn) = "toy_gs_dn"
gslist <- list(toy_gs_up, toy_gs_dn)
gscolc <- GSEABase::GeneSetCollection(gslist)
scordf <- multiscore(ranked, upSetColc = gscolc)
plotDispersion

Plot the score vs. dispersion for all samples

Description

This function takes the output from the `simpleScore()` function and generates scatter plots of score vs. dispersion for the total score, the up score and the down score of samples. If you wish to use the plotting function but with some customized inputs (instead of outputs from `simpleScore` function), you need to make sure the formats are the same. To be specific, you need to have columns names "TotalScore" "TotalDispersion" "UpScore" "UpDispersion" "DownScore" "DownDispersion" and rows names as samples.

Usage

plotDispersion(
  scoredf,
  annot = NULL,
  annot_name = "",
  sampleLabels = NULL,
  alpha = 1,
  size = 1,
  textSize = 1.2,
  isInteractive = FALSE
)

Arguments

- `scoredf` data.frame, generated using the `simpleScore()` function
- `annot` any numeric, character or factor annotation provided by the user that needs to be plot. Alternatively, this can be a character specifying the column of `scoredf` holding the annotation. Annotations must be ordered in the same way as the scores
- `annot_name` character, legend title for the annotation
- `sampleLabels` vector of character, sample names to display, ordered in the same way as samples are ordered in the `scoredf` data.frame and with labels for all samples. Samples whose labels should not be displayed should be left as empty strings or NAs. Default as NULL which means the projected points are not labelled.
- `alpha` numeric, set the transparency of points
- `size` numeric, set the size of each point
- `textSize` numeric, relative text sizes for title, labels, and axis values
- `isInteractive` Boolean, determine whether the plot is interactive

Value

A ggplot object
Examples

```r
ranked <- rankGenes(toy_expr_se)
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)
plotDispersion(scoredf)
plotDispersion(scoredf, isInteractive = TRUE)
```

---

**plotNull**

*Plot the empirically estimated null distribution and associated p-values*

**Description**

This function takes the results from function `generateNull()` and plots the density curves of permuted scores for the provided samples via `sampleNames` parameter. It can plot null distribution(s) for a single sample or multiple samples.

**Usage**

```r
plotNull(
  permuteResult,
  scoredf,
  pvals,
  sampleNames = NULL,
  cutoff = 0.01,
  textSize = 2,
  labelSize = 5
)
```

**Arguments**

- `permuteResult` A matrix, null distributions for each sample generated using the `generateNull()` function
- `scoredf` A dataframe, sing scores generated using the `simpleScore()` function
- `pvals` A vector, estimated p-values using the `getPvals()` function `permuteResult`, `scoredf` and `pvals` are the results for the same samples.
- `sampleNames` A character vector, sample IDs for which null distributions will be plotted
- `cutoff` numeric, the cutoff value for determining significance
- `textSize` numeric, size of axes labels, axes values and title
- `labelSize` numeric, size of label texts

**Value**

a `ggplot` object

**Author(s)**

Ruoqian Lyu
Examples

```r
ranked <- rankGenes(toy_expr_se)
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)
# find out what backends can be registered on your machine
BiocParallel:::registered()
# the first one is the default backend, and it can be changed explicitly.
permuteResult = generateNull(upSet = toy_gs_up, downSet = toy_gs_dn, ranked,
B = 10, seed = 1, useBPPARAM = NULL)
# call the permutation function to generate the empirical scores
# for B times.
pvals <- getPvals(permuteResult, scoredf)
# plot for all samples
plotNull(permuteResult, scoredf, pvals, sampleNames = names(pvals))
# plot for the first sample
plotNull(permuteResult, scoredf, pvals, sampleNames = names(pvals)[1])
```

**Description**

This function takes a single-column data frame, which is a single-column subset of the ranked matrix data generated using `rankGenes()` function, and the gene sets of interest as inputs. It plots the density of ranks for genes in the gene set and overlays a barcode plot of these ranks. Ranks are normalized by dividing them by the maximum rank. Densities are estimated using KDE.

**Usage**

```r
plotRankDensity(rankData, upSet,
downSet = NULL,
isInteractive = FALSE,
textSize = 1.5)
```

```r
## S4 method for signature 'ANY, vector, missing'
plotRankDensity(rankData, upSet,
downSet = NULL,
isInteractive = FALSE,
textSize = 1.5)
```

```r
## S4 method for signature 'ANY, GeneSet, missing'
plotRankDensity(rankData,
```

---

**plotRankDensity**

*Plot the densities of ranks for one sample*

---

### Description

This function takes a single-column data frame, which is a single-column subset of the ranked matrix data generated using `rankGenes()` function, and the gene sets of interest as inputs. It plots the density of ranks for genes in the gene set and overlays a barcode plot of these ranks. Ranks are normalized by dividing them by the maximum rank. Densities are estimated using KDE.

### Usage

```r
plotRankDensity(rankData, upSet,
downSet = NULL,
isInteractive = FALSE,
textSize = 1.5)
```

```r
## S4 method for signature 'ANY, vector, missing'
plotRankDensity(rankData, upSet,
downSet = NULL,
isInteractive = FALSE,
textSize = 1.5)
```

```r
## S4 method for signature 'ANY, GeneSet, missing'
plotRankDensity(rankData,
```
Arguments

rankData: one column of the ranked gene expression matrix obtained from the `rankGenes()` function, use `drop = FALSE` when subsetting the ranked gene expression matrix, see examples.

upSet: GeneSet object or a vector of gene Ids, up-regulated gene set

downSet: GeneSet object or a vector of gene Ids, down-regulated gene set

isInteractive: Boolean, determine whether the returned plot is interactive

textSize: numeric, set the size of text on the plot

Value

A ggplot object (or a plotly object) with a rank density plot overlayed with a barcode plot

Examples

```r
ranked <- rankGenes(toy_expr_se)
plotRankDensity(ranked[,2,drop = FALSE], upSet = toy_gs_up)
```
**plotRankDensity_intl**  
*Plot the densities of ranks for one sample*

Description

This function takes a single column data frame, which is a subset of the ranked data obtained from `rankGenes()` function and gene sets, and it returns plots visualising the density and the rugs of the ranks.

Usage

```r
plotRankDensity_intl(
  rankData,
  upSet,
  downSet = NULL,
  isInteractive = FALSE,
  textSize = 1.2
)
```

Arguments

- `rankData`: one column of the ranked gene expression matrix obtained from the `rankGenes()` function, use drop = FALSE when subsetting the ranked gene expression matrix, see examples.
- `upSet`: GeneSet object, up regulated gene set
- `downSet`: GeneSet object, down regulated gene set
- `isInteractive`: Boolean, determine whether the returned plot is interactive
- `textSize`: numeric, set the size of text on the plot

Value

A ggplot object (optionally interactive) demonstrating the rank density along with rug plot

See Also

"GeneSet"
plotScoreLandscape  

Plot landscape of two gene signatures scores

Description

This function takes two data frames which are outputs from the simpleScore() function and plots the relationship between the two gene set scores for samples in the gene expression matrix. Scoredf1 and Scoredf2 are two scoring results of the same set of samples against two different gene signatures. If you wish to use the plotting function but with some customized inputs (instead of outputs from the simpleScore function), you need to make sure the formats are the same. To be specific, you need to have column names "TotalScore" "TotalDispersion" "UpScore" "UpDispersion" "DownScore" "DownDispersion" and rows names as samples.

Usage

plotScoreLandscape(
  scoredf1,
  scoredf2,
  scorenames = c(),
  textSize = 1.2,
  isInteractive = FALSE,
  hexMin = 100
)

Arguments

- **scoredf1**: data.frame, result of the simpleScore() function which scores the gene expression matrix against a gene set of interest
- **scoredf2**: data.frame, result of the simpleScore() function which scores the gene expression matrix against another gene set of interest
- **scorenames**: character vector of length 2, names for the two scored gene set/signatures stored in scoredf1 and scoredf2
- **textSize**: numeric, set the text size for the plot, default as 1.5
- **isInteractive**: boolean, whether the plot is interactive, default as FALSE
- **hexMin**: integer, the threshold which decides whether hex bin plot or scatter plot is displayed, default as 100

Value

A ggplot object, a scatter plot, demonstrating the relationship between scores from two signatures on the same set of samples.
Examples

```r
ranked <- rankGenes(toy_expr_se)
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)
scoredf2 <- simpleScore(ranked, upSet = toy_gs_up)
plotScoreLandscape(scoredf, scoredf2)
```

Description

This function takes the output (ggplot object) of the function `plotScoreLandscape()` and a new dataset. It projects the new data points onto the landscape plot and returns a new ggplot object with projected data points.

Usage

```r
projectScoreLandscape(
  plotObj = NULL,
  scoredf1,
  scoredf2,
  annot = NULL,
  annot_name = NULL,
  subSamples = NULL,
  sampleLabels = NULL,
  isInteractive = FALSE
)
```

Arguments

- `plotObj`: a ggplot object, resulted from `plotScoreLandscape()`
- `scoredf1`: data.frame, result of the `simpleScore()` function which scores the gene expression matrix against a gene set of interest
- `scoredf2`: data.frame, result of the `simpleScore()` function which scores the gene expression matrix against another gene set of interest. Scores in `scoredf1` and `scoredf2` consist of the new data points that will be projected on the `plotObj` landscape plot.
- `annot`: any numeric, character or factor annotation provided by the user that needs to be plot. Alternatively, this can be a character specifying the column of `scoredf1` holding the annotation. Annotations must be ordered in the same way as the scores
- `annot_name`: character, legend title for the annotation
- `subSamples`: vector of character or indices for subsetting the `scoredfs`, default as NULL and all samples in `scoredfs` will be plotted. The subsetted samples are projected onto the landscape plot of `plotObj`.
**sampleLabels**  
vector of character, sample names to display, ordered in the same way as samples are ordered in the 'scoredfs' data.frames and with labels for all samples. Samples whose labels should not be displayed should be left as empty strings or NAs. Default as NULL which means the projected points are not labelled.

**isInteractive**  
boolean, whether the plot is interactive default as FALSE

**Value**  
New data points on the already plotted ggplot object from plotScoreLandscape()

**See Also**  
plotScoreLandscape()

```r
@examples  
ranked <- rankGenes(toy_expr_se)  
scoredf1 <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)  
scoredf2 <- simpleScore(ranked, upSet = toy_gs_up)  
psl <- plotScoreLandscape(scoredf1, scoredf2)  
projectScoreLandscape(psl,scoredf1, scoredf2)
```

**rankGenes**  
*Rank genes by the gene expression intensities*

**Description**  
The `rankGenes` function is a generic function that can deal with multiple types of inputs. Given a matrix of gene expression that has samples in columns, genes in rows, and values being gene expression intensity, `rankGenes` ranks gene expression intensities in each sample. It can also work with S4 objects that have gene expression matrix as a component (i.e ExpressionSet, DGEList, SummarizedExperiment). It calls the `rank` function in the base package which ranks the gene expression matrix by its absolute expression level. If the input is S4 object of DGEList, ExpressionSet, or SummarizedExperiment, it will extract the gene expression matrix from the object and rank the genes. The default `tiesMethod` is set to 'min'.

**Usage**  
```r
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```

```r
# S4 method for signature 'matrix'
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```

```r
# S4 method for signature 'data.frame'
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```

```r
# S4 method for signature 'DGEList'
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```

```r
# S4 method for signature 'ExpressionSet'
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```

```r
# S4 method for signature 'SummarizedExperiment'
rankGenes(expreMatrix, tiesMethod = "min", stableGenes = NULL)
```
scoredf_ccle_epi

**Arguments**

- `expresMatrix` : matrix, data.frame, ExpressionSet, DGEList or SummarizedExperiment storing gene expression measurements
- `tiesMethod` : character, indicating what method to use when dealing with ties
- `stableGenes` : character, containing a list of stable genes to be used to rank genes using expression of stable genes. This is required when using the stable genes dependent version of singscore (see details in `simpleScore`). Stable genes for solid cancers (carcinomas) and blood transcriptomes can be obtained using the `getStableGenes` function

**Value**

The ranked gene expression matrix that has samples in columns and genes in rows. Unit normalised ranks are returned if data is ranked using stable genes

**See Also**

- `getStableGenes`, `simpleScore`, `rank`, "ExpressionSet", "SummarizedExperiment", "DGEList"

**Examples**

```r
rankGenes(toy_expr_se) # toy_expr_se is a gene expression dataset

# ExpressionSet object
emat <- SummarizedExperiment::assay(toy_expr_se)
e <- Biobase::ExpressionSet(assayData = as.matrix(emat))
rankGenes(e)

#scoring using the stable version of singscore
rankGenes(e, stableGenes = c('2', '20', '25'))

</table>

**Description**

This data.frame stores pre-computed scores of the CCLE dataset Barretina et al calculated using the `simpleScore()` function against the epithelial gene signature from Tan, Tuan Zea et al. The data.frame has scores for 55 samples. Please refer to the vignettes for instructions on how to obtain the full datasets.
Usage

scoredf_cCLE_epi

Format

An object of class data.frame with 55 rows and 2 columns.

simpleScore

single-sample gene-set scoring method

Description

This function computes 'singscores' using an unmodified ranked gene expression matrix obtained from the rankGenes() function and a gene set or a pair of up-regulated and down-regulated gene sets. It returns a data.frame of scores and dispersions for each sample. The gene sets can be in vector format or as GeneSet objects (from GSEABase packages). If samples need to be scored against a single gene set, the upSet argument should be used to pass the gene set while the downSet argument is set to NULL. This setting is ideal for gene sets representing gene ontologies where the nature of the genes is unknown (up- or down-regulated).

Usage

simpleScore(
  rankData,
  upSet,
  downSet = NULL,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,vector,missing'
simpleScore(
  rankData,
  upSet,
  downSet = NULL,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
simpleScore

knownDirection = TRUE

## S4 method for signature 'matrix,GeneSet,missing'
simpleScore(
  rankData,
  upSet,
  downSet = NULL,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,vector,vector'
simpleScore(
  rankData,
  upSet,
  downSet = NULL,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

## S4 method for signature 'matrix,GeneSet,GeneSet'
simpleScore(
  rankData,
  upSet,
  downSet = NULL,
  subSamples = NULL,
  centerScore = TRUE,
  dispersionFun = mad,
  knownDirection = TRUE
)

Arguments

rankData A matrix object, ranked gene expression matrix data generated using the rankGenes() function (make sure this matrix is not modified, see details)

upSet A GeneSet object or character vector of gene IDs of up-regulated gene set or a gene set where the nature of genes is not known

downSet A GeneSet object or character vector of gene IDs of down-regulated gene set or NULL where only a single gene set is provided

subSamples A vector of sample labels/indices that will be used to subset the rankData matrix. All samples will be scored if not provided

centerScore A Boolean, specifying whether scores should be centered around 0, default as TRUE. Note: scores never centered if knownDirection = FALSE
dispersionFun  A function, dispersion function with default being mad
knownDirection  A boolean, determining whether the gene set should be considered to be directional or not. A gene set is directional if the type of genes in it are known i.e. up- or down-regulated. This should be set to TRUE if the gene set is composed of both up- AND down-regulated genes. Defaults to TRUE. This parameter becomes irrelevant when both upSet(Colc) and downSet(Colc) are provided.

Details

Signature scores can be computed using transcriptome-wide measurements or using a smaller set of measurements. If ranks are computed using the default invocation of rankgenes, the former method is applied where the rank of each gene in the signature is computed relative to all other genes in the dataset. Accuracy of this approximation of the relative expression of a gene will be improved if all or most transcripts are measured in the experiment. This was the approach proposed in the original manuscript of singscore (Foroutan M, Bhuva DD, et al 2018).

If instead a selected panel of genes is measured (such as from nanostring or RT-qPCR), a different rank approximation methods using a small set of stable genes can be used. This approach only requires measurements of genes in the signature and a small set of stable genes. This approach of scoring can be invoked by producing a rank matrix by passing in the stableGenes argument of rankGenes. Stable genes in solid cancers and in blood can be retrieved using getStableGenes. Upon providing a set of stable genes, rankGenes automatically ranks all genes relative to these stable genes. When simpleScore is provided with a rank matrix constructed using stable genes, it automatically computes scores using a new approach. Details of the set of stable genes, the new rank estimation approach and the new scoring approach will soon be published (manuscript in preparation).

Value

A data.frame consists of singscores and dispersions for all samples

Examples

```r
ranked <- rankGenes(toy_expr_se)
scoredf <- simpleScore(ranked, upSet = toy_gs_up, downSet = toy_gs_dn)
# toy_gs_up is a GeneSet object, alternatively a vector of gene ids may also
# be supplied.
```
singscore

**singscore: A package for deriving gene-set scores at a single sample level**

**Description**

The package provides functions for calculating gene-set enrichment scores at a single-sample level using gene expression data. It includes functions to perform hypothesis testing and provides visualisations to enable diagnosis of scores and gene sets along with visualisations to enable exploration of results.

**tgfβ_expr_10_se**

An example gene expression dataset

**Description**

A microarray gene expression dataset that was originally obtained from the integrated TGFβ-EMT data published by (Foroutan et al, 2017). (ComBat corrected values). `tgfb_expr_10` is a subset of the integrated TGFβ-EMT data consisting of 10 samples (4 TGFβ treated and 6 controls) each with expression values for 11900 genes.

**Usage**

`tgfβ_expr_10_se`

**Format**

A SummarizedExperiment object

**Source**

Foroutan et al, 2017

**References**

**Description**

A GeneSet object that contains the down-regulated genes of the TGFb-induced EMT gene signature that was derived by (Foroutan et al.,2017), using two meta-analysis techniques. The gene signature contains an up-regulated gene set (up-set) and a down-regulated gene set (down-set). Please refer to the vignettes for the steps to acquire the exact data object.

**Usage**

tgfb_gs_dn

**Format**

A GeneSet object
