Package ‘snapcount’

May 4, 2024

Type Package

Title R/Bioconductor Package for interfacing with Snaptron for rapid querying of expression counts

Version 1.16.0

Description snapcount is a client interface to the Snaptron webservice which support querying by gene name or genomic region. Results include raw expression counts derived from alignment of RNA-seq samples and/or various summarized measures of expression across one or more regions/genes per-sample (e.g. percent spliced in).

Depends R (>= 4.0.0)

Imports R6, httr, rlang, purrr, jsonlite, assertthat, data.table, Matrix, magrittr, methods, stringr, stats, IRanges, GenomicRanges, SummarizedExperiment

Suggests BiocManager, bit64, covr, knitr (>= 1.6), devtools, BiocStyle (>= 2.5.19), rmarkdown (>= 0.9.5), testthat (>= 2.1.0)

git_branch RELEASE_3_19
Description

snapcount is a client interface to the Snaptron webservice which supports querying by gene name or genomic region.

Details

Results include raw expression counts derived from alignment of RNA-seq samples and/or various summarized measures of expression across one or more regions/genes per-sample (e.g. percent spliced in).

To learn more about snapcount, check out the vignette: `browseVignettes(package = "snapcount")`
Package options

snapcount.host  Change the host that snapcount uses when connecting to Snaptron. Default: snaptron.cs.jhu.edu

snapcount.port  Change the port that snapcount uses when connecting to Snaptron. Default: 80

Author(s)

Maintainer: Rone Charles <rcharle8@jh.edu>

</tr>
</tbody>
</table>

Usage

Compilation

Format

An object of class environment of length 21.

Details

- gtex
- tcga
- srav2
- sra

See Also

[http://snaptron.cs.jhu.edu/data.html](http://snaptron.cs.jhu.edu/data.html) for more information about Snaptron compilations.

Examples

qb <- QueryBuilder(compilation = Compilation$gtex, regions = "KCNIP4")
query_jx(qb)
Coordinates

| Enum for Snaptron Coordinate modifiers |

Description

Enum for Snaptron Coordinate modifiers

Usage

Coordinates

Format

An object of class environment of length 4.

Fields

Exact  Return junctions whose start and end coordinates match the boundaries of the region requested.

Within  Return junctions whose start and end coordinates are within the boundaries of the region requested.

StartIsExactOrWithin  Return junctions whose start coordinate matches, or is within, the boundaries of the region requested.

EndIsExactOrWithin  Return junctions whose end coordinate matches, or is within, the boundaries of the region requested.

Examples

qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
qb <- set_coordinate_modifier(qb, Coordinates$Exact)
qb

from_url

Constructs aQueryBuilder object from the given url

Description

Constructs a QueryBuilder object from the given url

Usage

from_url(url)
**Arguments**

**url**

A well-formed URL preferably obtained from a call to the `uri_of_last_successful_request` function.

**Value**

Returns a `QueryBuilder` object with attributes set from the parsed URL.

**Examples**

```r
sb <- from_url("http://snaptron.cs.jhu.edu/gtex/snaptron?regions=CD99")
get_regions(sb)
get_compilation(sb)
```

---

**get_column_filters**

Get or set sample-related constraints for query

**Description**

Get or set sample-related constraints for query

**Usage**

```r
get_column_filters(qb)
set_column_filters(qb, ...)
```

**Arguments**

**qb**

A `QueryBuilder` object constructed using the `QueryBuilder` function

**...**

One or more boolean predicates as either strings or unevaluated expressions

**Value**

`get_column_filters` returns the current filters as a list of strings. `set_column_filters` returns a new `QueryBuilder` object with the column filters set to the value of `column_filters`.

**Examples**

```r
qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
# column filters set using a string
qb <- set_column_filters(qb, "SMTS == Brain")
get_column_filters(qb)
# column filters set using unevaluated expression
qb <- set_column_filters(qb, SMTS == "Spleen")
get_column_filters(qb)
```
get_compilation

Description
Get or set query compilation

Usage
get_compilation(qb)
set_compilation(qb, compilation)

Arguments
qb A QueryBuilder object constructed using the QueryBuilder function.
compilation A single string containing the name of the Snaptron data source. Any variant of
the Compilation enum can also be passed as an argument.

Value
get_compilation returns the current compilation as string. set_compilation returns a new
QueryBuilder object with the compilation set to the value of compilation.

Examples
qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
get_compilation(qb)
qb <- set_compilation(qb, Compilation$tcga)
get_compilation(qb)

get_coordinate_modifier

Description
Get or set coordinate modifiers for the query.

Usage
get_coordinate_modifier(qb)
set_coordinate_modifier(qb, coordinate_modifier)
get_regions

Arguments
- 
  qb
    aQueryBuilder object constructed using the QueryBuilder function.
  coordinate_modifier
    any of the variants of the Coordinates enum.

Value
- get_coordinate_modifier returns the current coordinate modifier as a string. set_coordinate_modifier returns a new QueryBuilder object with the coordinate modifier set to the value of coordinate_modifier.

Examples
- qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
- qb <- set_coordinate_modifier(qb, Coordinates$Within)
- get_coordinate_modifier(qb)

get_regions

Get or set query regions

Description
- Get or set query regions

Usage
- get_regions(qb)
- set_regions(qb, regions)

Arguments
- qb
  A QueryBuilder object constructed using the QueryBuilder function.
- regions
  Either a list of 1 more HUGO gene names as strings e.g. "BRCA1" or a Granges class object containing one or more genomic intervals (e.g. "chr1:1-1000").

Value
- get_regions returns the current regions as a list of strings. set_regions returns a new QueryBuilder object with the regions set to the value of regions.

Examples
- qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
- get_regions(qb)
- qb <- set_regions(qb, "chr1:1-1000")
- get_regions(qb)
- qb <- set_regions(qb, GenomicRanges::GRanges("chr1", "1-1000"))
- get_regions(qb)
get_row_filters

Get or set range-related constraints for query

Description

Get or set range-related constraints for query

Usage

get_row_filters(qb)

set_row_filters(qb, ...)

Arguments

qb a QueryBuilder object constructed using the QueryBuilder function.

... one or more boolean predicates as either strings or unevaluated expressions.

Value

get_row_filters returns the current row filters as list of strings. set_row_filters returns a new
QueryBuilder object with the row filters set to the value of row_filters.

Examples

qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
# row filters set as a string
qb <- set_row_filters(qb, "strand == +")
get_row_filters(qb)
# row filters set using unevaluated expression
qb <- set_row_filters(qb, strand == "+")
get_row_filters(qb)

get_sids

Get or set query sample ids

Description

Get or set query sample ids

Usage

get_sids(qb)

set_sids(qb, sids)
junction_inclusion_ratio

Arguments

qb                a QueryBuilder object constructed using the QueryBuilder function.
sids             a vector or 1 or more whole numbers to filter results on.

Value

get_sids returns the current sample ids as a vector of integers. set_sids returns a new QueryBuilder object with the sample ids set to the value of sids.

Examples

qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
qb <- set_sids(qb, c(1, 2, 3))
get_sids(qb)

junction_inclusion_ratio

Relative measure of splice variant usage similar to PSI that allows for 2 arbitrarily defined groups of junctions (not limited to cassette exons).

Description

Calculates a coverage summary statistic per sample of the normalized coverage difference between two sets of separate junctions defined by at least two basic queries and organized into two groups.

Usage

junction_inclusion_ratio(group1, group2, group_names = NULL)

Arguments

group1, group2  Each group is a list of 1 or more QueryBuilder objects

Details

The summary statistic is as follows: If the coverage of the first group is "A" and the second is "B":
JIR(A,B)=(A - B) / (A+B+1)
This is calculated for every sample that occurs in one or the other (or both) groups results.

Value

A DataFrame of samples, with their JIR score and metadata, which had > 0 coverage in at least one resulting row in at least one of the groups
Examples

```r
sb1 <- QueryBuilder(compilation = "srav2", regions = "chr2:29446395-30142858")
sb1 <- set_coordinate_modifier(sb1, Coordinates$Within)
sb1 <- set_row_filters(sb1, strand == "-"

sb2 <- QueryBuilder(compilation = "srav2", regions = "chr2:29416789-29446394")
sb2 <- set_coordinate_modifier(sb2, Coordinates$Within)
sb2 <- set_row_filters(sb2, strand == "-"

junction_inclusion_ratio(list(sb1), list(sb2))
```

**junction_intersection**  
Get the intersection of junctions from 2 or more compilations which are on the same reference

Description

This function operates similar to the junction_union() function, i.e. it is cross compilation and merging of the same junction from multiple compilations will be handled exactly the same way. But instead of every junction which appears in at least one compilation, only the junctions which appear in every compilation will be returned.

Usage

```r
junction_intersection(...)
```

Arguments

...  
One or more QueryBuilder objects

Value

A RangedSummarizedExperiment of junctions common across compilations

See Also

`junction_union()`

Examples

# Using query builder wrappers
sb1 <- QueryBuilder(compilation = "gtex", regions = "chr1:1879786-1879786")
sb1 <- set_coordinate_modifier(sb1, Coordinates$EndIsExactOrWithin)
sb1 <- set_row_filters(sb1, strand == "-"

sb2 <- QueryBuilder(compilation = "tcga", regions = "chr1:1879786-1879786")
sb2 <- set_coordinate_modifier(sb2, Coordinates$EndIsExactOrWithin)
sb2 <- set_row_filters(sb2, strand == "-"

junction_intersection(sb1, sb2)
junction_union

Get the union of junctions from 2 or more compilations which are on the same reference

Description

This function queries 2 or more compilations which are on the same reference version (e.g. hg38) and merges the resulting junctions into a single output table, unioning the sample coverage columns and the snaptron_id (jx ID) columns (the latter delimiter will be ":"). All sample IDs will be disjoint between compilations.

Usage

junction_union(...)

Arguments

... One or more QueryBuilder objects

Details

Union is based on the following fields (combined into a comparison key):

- group
- chromosome
- start
- end
- strand

The goal is to have a single list of junctions where every junction occurs in at least one compilation and if a junction occurs in > 1 compilations it still only has a single row representing all the samples across compilations that it appears in. Sample aggregate statistics will be recalculated for junctions which are merged across all samples from all compilations:

- sample_count
- coverage_sum
- coverage_avg
- coverage_median

Value

A RangedSummarizedExperiment of junctions appearing in at least one compilation

See Also

junction_intersection()
Examples

# Using query builder wrappers
sb1 <- QueryBuilder(compilation = "gtex", regions = "chr1:1879786-1879786")
sb1 <- set_coordinate_modifier(sb1, Coordinates$EndIsExactOrWithin)
sb1 <- set_row_filters(sb1, strand == "-")

sb2 <- QueryBuilder(compilation = "tcga", regions = "chr1:1879786-1879786")
sb2 <- set_coordinate_modifier(sb2, Coordinates$EndIsExactOrWithin)
sb2 <- set_row_filters(sb2, strand == "-")

junction_union(sb1, sb2)

percent_spliced_in

Relative measure of splice variant usage, limited currently to cassette exon splice variants

Description

Similar to the JIR, this calculates Percent Spliced In (PSI) statistics for the definition of 2 different groups: inclusion and exclusion. Currently this function only supports the cassette exon use case.

Usage

percent_spliced_in(
  inclusion_group1, inclusion_group2, exclusion_group, 
  min_count = 20, group_names = NULL
)

Arguments

  inclusion_group1, inclusion_group2, exclusion_group
    Where each is a list of 1 or more QueryBuilder objects

  min_count
    minimum total count (denominator) required to not be assigned -1

  group_names
    Optional vector of strings representing the group names

Details

Inclusion typically defines 2 basic queries, one for the junction preceding the cassette exon, and the second for the junction following the cassette exon. The exclusion group contains one basic query which defines the junction which skips the cassette exon.

The PSI itself is implemented as:

\[
\text{PSI}(\text{inclusion1, inclusion2, exclusion}) = \frac{\text{mean(inclusion1, inclusion2)}}{(\text{mean(inclusion1, inclusion2)} + \text{exclusion})}
\]

where each term denotes the coverage of junctions that resulted from the basic queries in that group in the current sample.
**QueryBuilder**

**Value**

A DataFrame of samples, with their PSI score and metadata, which had > 0 coverage in at least one resulting row in at least one of the groups

**Examples**

```r
in1 <- QueryBuilder(compilation = "srav2", regions = "chr1:94468008-94472172")
in1 <- set_coordinate_modifier(in1, Coordinates$Exact)
in1 <- set_row_filters(in1, strand == "+")

in2 <- QueryBuilder(compilation = "srav2", regions = "chr1:94468008-94472172")
in2 <- set_coordinate_modifier(in2, Coordinates$Exact)
in2 <- set_row_filters(in2, strand == "+")

ex <- QueryBuilder(compilation = "srav2", regions = "chr1:94468008-94475142")
ex <- set_coordinate_modifier(ex, Coordinates$Exact)
ex <- set_row_filters(ex, strand == "+")

percent_spliced_in(list(in1), list(in2), list(ex))
```

---

**QueryBuilder**  
Construct a QueryBuilder object given a compilation and one or regions.

**Description**

Construct a QueryBuilder object given a compilation and one or regions.

**Usage**

```r
QueryBuilder(compilation, regions)
```

**Arguments**

- **compilation**  
  A single string containing the name of the Snaptron data source. Any variant of the Compilation enum can also be passed an argument.

- **regions**  
  Either a list of 1 more HUGO gene names as strings e.g. "BRCA1" or a Granges class object containing one or more geneomic intervals (e.g. "chr1:1-1000").

**Value**

A QueryBuilder object.
query_jx

Query Junctions/Genes/Exons

Description

Given one or more gene names or genomic range intervals it will return a list of 0 or more genes, junctions, or exons (depending on which query form is used) which overlap the ranges.

Usage

query_jx(sb, return_rse = TRUE, split_by_region = FALSE)
query_gene(sb, return_rse = TRUE, split_by_region = FALSE)
query_exon(sb, return_rse = TRUE, split_by_region = FALSE)

Arguments

sb
A SnaptronQueryBuilder object

return_rse
Should the query data be returned as a simple data frame or converted to a
RangedSummarizedExperiment.

split_by_region
By default the results from multiple queries will be returned in a RangedSummarizedExperiment
object with a rowData entry for each, labeling each result row according to the
query it resulted from. However, if this is set to TRUE, the result will be a list of
RangedSummarizedExperiment objects, one per original interval/gene. This latter
option may be useful, but it requires a separate copy of the sample metadata
for each original interval/gene.

Value

Functions will return either a RangedSummarizedExperiment or data.table depending on whether
the return_rse parameter is set to TRUE or FALSE.
## Examples

```r
# Construct a QueryBuilder object
qb <- QueryBuilder(compilation = "gtex", regions = "chr1:1-100000")
qb <- set_row_filters(qb, samples_count >= 20)
query_jx(qb)

qb <- set_row_filters(qb, NULL)
qb <- set_column_filters(qb, SMTS == "Brain")
query_gene(qb)
```

---

**shared_sample_counts**  
*Shared Sample Count (SSC): counts total number of samples in which 2 different junctions both occur in.*

---

### Description

This produces a list of user-specified groups and the read coverage of the junctions in all the samples which were shared across all the basic queries occurring in each group.

### Usage

```r
shared_sample_counts(..., group_names = NULL)
```

### Arguments

- `...`  
  One or more lists of QueryBuilder objects

- `group_names`  
  Optional vector of character strings representing group names

### Details

Example: User defines a single group of junctions "GroupA" made up of 2 separate regions (two basic queries).

An SSC query will return a single line for GroupA which will have the total number of samples which had at least one junction which was returned from both basic queries. It will also report a summary statistic of the total number of groups which had one or more samples that were shared across the basic queries, in this case it would be 1. Also, it will report the number of groups which had at least one shared sample and which had matching junctions (from the query) which were fully annotated.

This function can be used to determine how much cross-sample support there is for a particular junction configuration (typically a cassette exon).

### Value

A DataFrame of results based on the list of groups passed in via "group_names". Each group is reported with the # of unique samples which occurred in all of its defined set of related basic queries (e.g. two inclusion basic queries in a cassette exon scenario).
tissue_specificity

Examples

g1 <- QueryBuilder(compilation = "gtex", regions = "chr1:1879786-1879786")
g1 <- set_coordinate_modifier(g1, Coordinates$EndIsExactOrWithin)
g1 <- set_row_filters(g1, strand == "-")

g2 <- QueryBuilder(compilation = "gtex", regions = "chr1:1879903-1879903")
g2 <- set_coordinate_modifier(g2, Coordinates$StartIsExactOrWithin)
g2 <- set_row_filters(g2, strand == "-"")

ssc <- shared_sample_counts(list(g1, g2))

tissue_specificity

Tissue Specificity (TS): produces a list of samples with their tissues marked which either contain queried junctions (1) or not (0); can be used as input to significance testing methods such as Kruskal-Wallis to look for tissue enrichment (currently only works for the GTEx compilation).

Description

Lists the number of samples labeled with a specific tissue type. Samples are filtered for ones which have junctions across all the user-specified groups. That is, if a sample only appears in the results of some of the groups (from their basic queries) it will be assigned a 0, otherwise if it is in all of the groups’ results it will be assigned a 1. This is similar to the SSC high level query type, but doesn’t sum the coverage.

Usage

tissue_specificity(..., group_names = NULL)

Arguments

... One or more QueryBuilder objects

Arguments

... One or more QueryBuilder objects

group_names Optional vector of strings representing the group names

Details

The samples are then grouped by their tissue type (e.g. Brain). This is useful for determining if there’s an enrichment for a specific tissue in the set of junctions queried. Results from this can be fed to a statistical test, such as the Kruskal-wallis non-parametric rank test. This query is limited to GTEx only, due to the fact that GTEx is one of the few compilations that has consistent and complete tissue metadata.

Value

A DataFrame of all samples in the compilation with either a 0 or 1 indicating their occurrence and shared status (if > 1 group passed in). Occurrence here is if the sample has at least one result with > 0 coverage, and further, if > 1 group is passed in, then if it occurs in the results of all groups. Also includes the sample tissue type and sample_id.
Examples

```r
in1 <- QueryBuilder(compilation = "gtex", regions = "chr4:20763023-20763023")
in1 <- set_coordinate_modifier(in1, Coordinates$EndIsExactOrWithin)
in1 <- set_row_filters(in1, strand == "-")

in2 <- QueryBuilder(compilation = "gtex", regions = "chr4:20763098-20763098")
in2 <- set_coordinate_modifier(in2, Coordinates$StartIsExactOrWithin)
in2 <- set_row_filters(in2, strand == "-")

tissue_specificity(list(in1, in2))
```

**uri_of_last_successful_request**

Return the URI of the last successful request to Snaptron

Description

This function can be paired with the `from_url` method from the QueryBuilder class, allowing users to share sources of data from Snaptron.

Usage

```r
uri_of_last_successful_request()
```

Value

URI of last successful request to Snaptron or NULL if there have not been any successful requests.

Examples

```r
qb <- QueryBuilder(compilation = "gtex", regions = "CD99")
query_jx(qb)
uri_of_last_successful_request()
```
