Package ‘updateObject’

May 30, 2024

Title  Find/fix old serialized S4 instances
Description  A set of tools built around updateObject() to work with old serialized S4 instances. The package is primarily useful to package maintainers who want to update the serialized S4 instances included in their package. This is still work-in-progress.

biocViews  Infrastructure, DataRepresentation

URL  https://bioconductor.org/packages/updateObject

BugReports  https://github.com/Bioconductor/updateObject/issues

Version  1.8.0
License  Artistic-2.0
Encoding  UTF-8

Depends  R (>= 4.2.0), methods, BiocGenerics (>= 0.47.1), S4Vectors
Imports  utils, digest

Suggests  GenomicRanges, SummarizedExperiment, InteractionSet, SingleCellExperiment, MultiAssayExperiment, TimiRGeN, testthat, knitr, rmarkdown, BiocStyle

SystemRequirements  git

VignetteBuilder  knitr

**bump_pkg_version**

**Bump the version of a package**

**Description**

Use `bump_pkg_version()` to bump the version of a package.

**Usage**

```r
bump_pkg_version(pkgpath=".", update.Date=FALSE)
```

**Arguments**

- **pkgpath**
  - The path (as a single string) to the top-level directory of an R package source tree.

- **update.Date**
  - TRUE or FALSE. If TRUE then the Date field (if present) gets updated to the current date.

**Value**

An invisible NULL.

**See Also**

- `updatePackageObjects` which uses `bump_pkg_version` internally when `bump.Version=TRUE`.
- `git_commit` for an example.

**Examples**

```r
## Create dummy R package:
create_dummy_pkg <- function(desc, pkgpath) {
  dir.create(pkgpath)
  descpath <- file.path(pkgpath, "DESCRIPTION")
  write.dcf(rbind(desc), descpath)
  descpath
}

pkgname <- "Dummy"
desc <- c(
```
git-utils

Convenience Git-related utility functions used by updateBiocPackageRepoObjects()

Description

prepare_git_repo_for_work() and git_commit() are used internally by updateBiocPackageRepoObjects() to perform Git operations.

Usage

prepare_git_repo_for_work(repopath=".", branch=NULL, git=NULL, use.https=FALSE)

git_commit(repopath=".", commit_msg, push=FALSE, 
git=NULL, user_name=NULL, user_email=NULL)

Arguments

repopath

The path (as a single string) to the local Git repository of a Bioconductor package.

If the specified path exists, prepare_git_repo_for_work() will check that it’s a workable Git repo (i.e. contains no uncommitted changes). If that’s the case then it will call git pull on it, otherwise it will return an error.

If the specified path does not exist, prepare_git_repo_for_work() will try to infer the package name from repopath and clone it from git.bioconductor.org.
branch

The branch (as a single string) of the Git repository to work on. If NULL, then the current branch is used (if repopath already exists) or the default branch is used (if repopath does not exist and needs to be cloned).

git

The path (as a single string) to the git command if it’s not in the PATH.

use.https

By default, `git clone git@git.bioconductor.org:packages/MyPackage` is used to clone a package repo from the Bioconductor Git server. Note that this works only for authorized maintainers of package `MyPackage`. By setting `use.https` to TRUE, the package will be cloned instead from `https://git.bioconductor.org:packages/MyPackage` which should work for anybody, but then pushing back the changes to the package won’t be possible.

commit_msg

The Git commit message.

push

Whether to push the changes or not. Changes are committed but not pushed by default. You need push access to the package Git repository at `git.bioconductor.org` in order to use push=TRUE.

user_name, user_email

Set the Git user name and/or email to use for the commit. This overrides the Git user name and/or email that the git command would otherwise use. See the COMMIT INFORMATION section in `system2("git", c("commit", "--help"))` for the details about where the git command normally takes this information from.

Value

`prepare_git_repo_for_work()` returns FALSE if the supplied path already exists, and TRUE if it didn’t exist and needed to be cloned.

`git_commit()` returns an invisible NULL.

See Also

- `updateBiocPackageRepoObjects` which uses `prepare_git_repo_for_work` and `git_commit` internally.
- `bump_pkg_version`.

Examples

```r
repopath <- file.path(tempdir(), "IdeoViz")

## We must use HTTPS access to clone the package because we are
## not maintainers of the IdeoViz package. A more realistic situation
## would be to use `prepare_git_repo_for_work()` on a package that we
## maintain, in which case 'use.https=TRUE' would not be needed:
prepare_git_repo_for_work(repopath, use.https=TRUE)

bump_pkg_version(repopath, update.Date=TRUE)

git_commit(repopath, commit_msg="version bump", push=FALSE)

unlink(repopath, recursive=TRUE)
```
updateBiocPackageRepoObjects

Update the serialized objects contained in a Bioconductor package Git repository or in a set of Bioconductor package Git repositories

Description

updateBiocPackageRepoObjects() and updateAllBiocPackageRepoObjects() are wrappers to updatePackageObjects() and updateAllPackageObjects() that take care of committing and pushing the changes made to the package(s).

Usage

updateBiocPackageRepoObjects(repopath=".", branch=NULL, filter=NULL, commit_msg=NULL, push=FALSE, remove.clone.on.success=FALSE, git=NULL, use.https=FALSE, user_name=NULL, user_email=NULL)

updateAllBiocPackageRepoObjects(all_repopaths=".", skipped_repos=NULL, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repopath</td>
<td>The path (as a single string) to the local Git repository of a Bioconductor package. See ?prepare_git_repo_for_work for more information.</td>
</tr>
<tr>
<td>branch</td>
<td>The branch (as a single string) of the Git repository to work on. See ?prepare_git_repo_for_work for more information.</td>
</tr>
<tr>
<td>filter</td>
<td>See ?updatePackageObjects.</td>
</tr>
<tr>
<td>commit_msg</td>
<td>The Git commit message. By default &quot;Pass serialized S4 instances thru updateObject()&quot; is used.</td>
</tr>
<tr>
<td>push</td>
<td>Whether to push the changes or not. Changes are committed but not pushed by default. You need push access to the package Git repository at git.bioconductor.org in order to use push=TRUE.</td>
</tr>
<tr>
<td>remove.clone.on.success</td>
<td>Whether to remove the Git clone on success or not. Only applies if repopath does not exist and needs to be cloned.</td>
</tr>
<tr>
<td>git, use.https</td>
<td>See ?prepare_git_repo_for_work.</td>
</tr>
<tr>
<td>user_name, user_email</td>
<td>See ?git_commit.</td>
</tr>
<tr>
<td>all_repopaths</td>
<td>Character vector of paths to local Git repositories of Bioconductor packages.</td>
</tr>
<tr>
<td>skipped_repos</td>
<td>Character vector of repository paths to ignore.</td>
</tr>
<tr>
<td>...</td>
<td>updateAllBiocPackageRepoObjects() walks over the all_repopaths vector and calls updateBiocPackageRepoObjects() on each repository path. All the arguments in ... are passed down to updateBiocPackageRepoObjects().</td>
</tr>
</tbody>
</table>
Value

updateBiocPackageRepoObjects() and updateAllBiocPackageRepoObjects() are wrappers to updatePackageObjects() and updateAllPackageObjects(), respectively, and return the same value.

See Also

- updatePackageObjects and updateAllPackageObjects.
- Utility functions prepare_git_repo_for_work and git_commit which are used internally by updateBiocPackageRepoObjects to perform the Git operations.

Examples

```r
# updateBiocPackageRepoObjects()
# ------------------------------------------
# Typical use, assuming MyPackage is a Bioconductor package that you maintain:
# Not run:
repath <- file.path(tempdir(), "MyPackage")
updateBiocPackageRepoObjects(repath, push=TRUE)
# End(Not run)

# Note that by default `updateBiocPackageRepoObjects()` does NOT try to push the changes to git.bioconductor.org. Only the authorized maintainers of MyPackage can do that. In the examples below we must use HTTPS access to clone the package because we are not maintainers of the CellBench or BiocGenerics packages. Also we don't use 'push=TRUE' because we are not allowed to do that (it wouldn't work anyways).

# On a package with a mix of RDS and RDA files:
repath <- file.path(tempdir(), "CellBench")
updateBiocPackageRepoObjects(repath, branch="RELEASE_3_13",
   remove.clone.on.success=TRUE,
   use.https=TRUE)

# On a package with no serialized objects:
repath <- file.path(tempdir(), "BiocGenerics")
updateBiocPackageRepoObjects(repath, branch="RELEASE_3_13",
   remove.clone.on.success=TRUE,
   use.https=TRUE)

# Note that the RELEASE_3_13 branch of all Bioconductor packages got frozen in October 2021. The above examples are for illustrative purpose only. A more realistic situation would be to use updateBiocPackageRepoObjects() on the development version (i.e. the master branch) of a package that you maintain, and to push the changes by calling the function with 'push=TRUE'.
```
## updateAllBiocPackageRepoObjects()

Let's assume that the current directory is populated with the Git repositories of all Bioconductor software packages and that we have push access to them:

```r
ALL_REPOS <- dir()  # get list of package repos to update

READ_RDS_FAILURE <- c(
  "BindingSiteFinder",
  "ChIPpeakAnno",
  "drugTargetInteractions"
)

)

## End(Not run)
```

updatePackageObjects  Update the serialized objects contained in a package or in a set of packages

Description

Use `updatePackageObjects()` to update all the serialized objects contained in a package.
Use `updateAllPackageObjects()` to update all the serialized objects contained in a set of packages.

Usage

```
updatePackageObjects(pkgpath=".", filter=NULL,
                      dry.run=FALSE, bump.Version=FALSE)

updateAllPackageObjects(all_pkgpaths, skipped_pkgs=NULL, filter=NULL,
                        dry.run=FALSE, bump.Version=FALSE)
```

Arguments

- `pkgpath` The path (as a single string) to the top-level directory of an R package source tree.
- `filter`, `dry.run` These arguments are passed down to `updateSerializedObjects()`. See `?updateSerializedObjects` for the details.
updatePackageObjects

bump.Version TRUE or FALSE. If TRUE and if some RDS or RDA files in the package actually get updated by updateSerializedObjects(), then the package version will get bumped, that is, the Version field in its DESCRIPTION file will get bumped from X.Y.Z to X.Y.(Z+1). For example, version 2.0.9 will become 2.0.10. Additionally, the Date field (if present) will get updated to the current date.

all_pkgpaths Character vector of package paths.
skipped_pkgs Character vector of package paths to ignore.

Value

updatePackageObjects() returns the value returned by its call to updateSerializedObjects(). See ?updateSerializedObjects for the details.

updateAllPackageObjects() returns a named integer vector parallel to all_pkgpaths.

See Also

• The updateSerializedObjects function which is the workhorse behind updatePackageObjects.
• updateBiocPackageRepoObjects and updateAllBiocPackageRepoObjects which are wrapper functions that also take care of committing and pushing the changes made to the packages.
• The bump_pkg_version function which is used internally by updatePackageObjects and updateAllPackageObjects when bump.Version=TRUE.

Examples

```
## A SIMPLE updatePackageObjects() EXAMPLE
## -----------------------------------------------------------

## DemoPackage is a small demo package (contained in the updateObject package) with some old serialized GRanges objects in it.
pkgname <- "DemoPackage"
pkgpath0 <- system.file(pkgname, package="updateObject")

## Let's copy DemoPackage to a writable location.
pkgpath <- file.path(tempdir(), pkgname)
file.copy(pkgpath0, dirname(pkgpath), recursive=TRUE)

## Note that, in order to update the GRanges objects contained in DemoPackage, updatePackageObjects() will need to attach the GenomicRanges package. That's because this is where the GRanges class and updateObject() method for GRanges objects are both defined. See '?updateSerializedObjects' for more information. Also note that we don't need to perform two passes ("dry run" + "real run"), one pass is enough. Here we show the 2-pass procedure for illustrative purpose only.

## 1st pass: dry run
code <- updatePackageObjects(pkgpath, dry.run=TRUE)
code # a non-negative code means everything went fine
```
## 2nd pass: do it for good!
updatePackageObjects(pkgpath, bump.Version=TRUE)

## An additional run would only confirm that there's nothing left
## to update.
code <- updatePackageObjects(pkgpath)
code # 0 (no files to update)

unlink(pkgpath, recursive=TRUE)

## FIND CANDIDATE PACKAGES IN CURRENT DIRECTORY
## ---------------------------------------------------------------------
## Not run:
## In this example we perform a "dry run" with updateAllPackageObjects()
## to find all the packages in a directory that contain old serialized
## objects.

## Let's assume that the current directory is populated with package
## git clones:
all_pkgs <- dir() # get list of packages

## If we know that some packages are going to cause problems, we should
## skip them. Note that we could just do
##
## all_pkgs <- setdiff(all_pkgs, SKIPPED_PKGS)
##
## for this. However, by using the 'skipped_pkgs' argument, all the
## packages in the original 'all_pkgs' will be represented in the
## returned vector, including the skipped packages:
SKIPPED_PKGS <- c(
  "BaalChIP", "BIGGR", "CytoTree", "gwascat",
  "mirIntegrator", "oposSOM", "PPF", "ROntoTools", "SLGI"
)

## --- Without a filter ---

## updateAllPackageObjects() will stop with an error if a package is
## required but not installed. The user is responsible for installing
## all the required packages (this is admittedly hard to know in advance).
codes <- updateAllPackageObjects(all_pkgs, skipped_pkgs=SKIPPED_PKGS, dry.run=TRUE)

sessionInfo() # many packages
table(codes)

## The above code was successfully run in the MEAT0 folder on nebbiolo1
## (BioC 3.15, 2007 packages) on Nov 18, 2021:
## - took about 14 min
## - loaded 1190 packages (as reported by sessionInfo())
## - required about 9GB of RAM
##
## > table(codes)
## codes
```
## codes
## -3 -2 -1 0 1 2 3 4 5 6 7 8 9 10
##  4 15 66 1549 240 90 46 28 7 5 4 3 3 1
## 13 18 20 23 125
##  2 1 1 1 1
##```
## > sum(codes > 0) / length(codes)
## [1] 0.2094823
## 21

--- With a filter ---

We want to filter on the presence of the **word** "DataFrame" in
the output of `updateObject( , check=FALSE, verbose=TRUE)`. We can't
just set 'filter' to "DataFrame" for that as this would also produce
matches in the presence of strings like "AnnotatedDataFrame":
```
filter <- "\bDataFrame\b"
```
```
codes <- updateAllPackageObjects(all_pkgs, skipped_pkgs=SKIPPED_PKGS,
                                  filter=filter,
                                  dry.run=TRUE)
```
```
## End(Not run)
```

---

### updateSerializedObjects

**Update the serialized objects contained in a directory**

#### Description

Use `updateSerializedObjects()` to find and update all the serialized objects contained in a
directory. This is the workhorse behind higher-level functions `updatePackageObjects()` and family
(`updateAllPackageObjects()`, `updateBiocPackageRepoObjects()`, and `updateAllBiocPackageRepoObjects()`).

#### Usage

```
updateSerializedObjects(dirpath=".", recursive=FALSE,
                        filter=NULL, dry.run=FALSE)
```

```
## Low-level utilities upon which updateSerializedObjects() is built:
collect_rds_files(dirpath=".", recursive=FALSE)
collect_rda_files(dirpath=".", recursive=FALSE)
update_rds_file(filepath, filter=NULL, dry.run=FALSE)
update_rda_file(filepath, filter=NULL, dry.run=FALSE)
```
updateSerializedObjects

Arguments

dirpath The path (as a single string) to an arbitrary directory.
recursive TRUE or FALSE. Should the directory be searched recursively to find the objects to update? By default the directory is not searched recursively.
filter NULL (the default) or a single string containing a regular expression. When filter is set, only objects for which there is a match in the output of updateObject(object, check=FALSE, verbose=TRUE) actually get replaced with the object returned by the updateObject call. See Details section below for more on this.
Note that the pattern matching is case sensitive.
dry.run TRUE or FALSE. By default, updated objects are written back to their original file. Set dry.run to TRUE to perform a trial run with no changes made.
filepath The path (as a single string) to a file containing serialized objects. This must be an RDS file (for update_rds_file) or RDA file (for update_rda_file).

Details

update_rds_file() and update_rds_file() use updateObject() internally to update individual R objects.
If no filter is specified (the default), each object is updated with object <- updateObject(object, check=FALSE). If that turns out to be a no-op, then code 0 ("nothing to update") is returned. Otherwise 1 is returned.
If a filter is specified (via the filter argument) then updateObject(object, check=FALSE, verbose=TRUE) is called on each object and the output of the call is captured with capture.output(). Only if the output contains a match for filter is the object replaced with the object returned by the call. If this replacement turns out to be a no-op, or if the output contained no match for filter, then code 0 ("nothing to update") is returned. Otherwise 1 is returned.
The pattern matching is case sensitive.
Note that determining whether a call to updateObject() is a no-op or not is done by calling digest::digest() on the original object and object returned by updateObject(), and by comparing the 2 hash values. This is a LOT MORE reliable than using identical() which is notoriously unreliable!

Value

updateSerializedObjects() returns a single integer which is the number of updated files or a negative error code (-2 if loading an RDS or RDA file failed, -1 if updateObject() returned an error).
collect_rds_files() and collect_rda_files() return a character vector of (relative) file paths.
update_rds_file() and update_rda_file() return a single integer which is one of the following codes:
-2 if loading the RDS or RDA file failed;
-1 if updateObject() returned an error;
0 if there was nothing to update in the file;
1 if the file got updated.
See Also

- The `updatePackageObjects` function which is just a thin wrapper around `updateSerializedObjects`.
- The `updateObject` generic function in the `BiocGenerics` package.
- The `capture.output` function in the `utils` package.
- The `digest` function in the `digest` package.

Examples

dirpath <- system.file("extdata", package="updateObject")

## WITHOUT A FILTER
## -----------------------------------------------
## updateSerializedObjects() prints one line per processed file:
updateSerializedObjects(dirpath, recursive=TRUE, dry.run=TRUE)

## Note that updateSerializedObjects() needs to attach/load the packages
## in which the classes of the objects to update are defined. These
## packages are: GenomicRanges for GRanges objects, SummarizedExperiment
## for SummarizedExperiment objects, and InteractionSet for GInteractions
## objects. This means that sessionInfo() will typically report more
## attached and loaded packages after a updateSerializedObjects() run
## than before:
sessionInfo()

## Also updateSerializedObjects() will raise an error if it fails to
## attach or load a package (typically because the package is missing).
## It will NOT try to install the package.

## -----------------------------------------------
## WITH A FILTER
## -----------------------------------------------

## We want to filter on the presence of the **word** "DataFrame" in
## the output of `updateObject( , check=FALSE, verbose=TRUE)`.
## We can't
## just set 'filter' to "DataFrame" for that as this would also produce
## matches in the presence of strings like "AnnotatedDataFrame":
filter <- "\bDataFrame\b"

updateSerializedObjects(dirpath, recursive=TRUE, filter=filter, dry.run=TRUE)
